# Package 'medfate'

September 14, 2022

**Type** Package

**Title** Mediterranean Forest Simulation

**Version** 2.8.0

**Date** 2022-08-31

**Description**
Functions to simulate Mediterranean forest functioning and dynamics using cohort-based description of vegetation [De Caceres et al. (2015) <doi:10.1016/j.agrformet.2015.06.012>; De Caceres et al. (2021) <doi:10.1016/j.agrformet.2020.108233>].

**License** GPL (>= 2)

**URL** https://emf-creaf.github.io/medfate/

**LazyLoad** yes

**Depends** R (>= 3.5.0)

**Imports** ggplot2, meteoland (>= 0.8.1), Rcpp (>= 1.0.6), shiny

**Suggests** testthat (>= 3.0.0), knitr, rmarkdown

**LinkingTo** Rcpp, meteoland

**Encoding** UTF-8

**NeedsCompilation** yes

**RoxygenNote** 6.1.1

**BugReports** https://github.com/emf-creaf/medfate/issues

**Config/testthat/edition** 3

**LazyData** true

`biophysics` *Physical and biophysical utility functions*

---

## Description

Utility functions for the calculation of biophysical variables.

## Usage

```
biophysics_irradianceToPhotonFlux(I, lambda)
biophysics_leafTemperature(absRad, airTemperature, u, E, leafWidth = 1.0)
biophysics_leafTemperature2(SWRabs, LWRnet, airTemperature, u, E, leafWidth = 1.0)
biophysics_leafVapourPressure(leafTemp, leafPsi)
biophysics_radiationDiurnalPattern(t, daylength)
biophysics_temperatureDiurnalPattern(t, tmin, tmax,
                                     tminPrev, tmaxPrev, tminNext, daylength)
biophysics_waterDynamicViscosity(temp)
```

## Arguments

| | |
|---|---|
| `I` | Irradiance (in W*m-2). |
| `lambda` | Wavelength (in nm). |
| `u` | Wind speed above the leaf boundary layer (in m/s). |
| `airTemperature` | Air temperature (in ºC). |

| | |
|---|---|
| `tmin, tmax` | Minimum and maximum daily temperature (ºC). |
| `tminPrev, tmaxPrev, tminNext` | Maximum and minimum daily temperatures of the previous and following day (ºC). |
| `absRad` | Absorbed long- and short-wave radiation (in W·m-2). |
| `SWRabs` | Absorbed short-wave radiation (in W·m-2). |
| `LWRnet` | Net long-wave radiation balance (in W·m-2). |
| `E` | Transpiration flow (in mmol H20·m-2·s-1) per one sided leaf area basis. |
| `leafWidth` | Leaf width (in cm). |
| `t` | Time of the day (in seconds). |
| `daylength` | Day length (in seconds). |
| `temp` | Temperature (ºC). |
| `leafTemp` | Leaf temperature (ºC). |
| `leafPsi` | Leaf water potential (MPa). |

## Details

Function `biophysics_leafTemperature` calculates leaf temperature according to energy balance equation given in Campbell and Norman (1988). Function `biophysics_radiationDiurnalPattern` follows the equations given in Liu and Jordan (1960). Function `biophysics_temperatureDiurnalPattern` determines diurnal temperature pattern assuming a sinusoidal pattern with T = Tmin at sunrise and T = (Tmin+Tmax)/2 at sunset and a linear change in temperature between sunset and Tmin of the day after (McMurtrie et al. 1990). Function `biophysics_waterDynamicViscosity` calculates water dynamic viscosity following the Vogel (1921) equation.

## Value

Values returned for each function are:

- `biophysics_leafTemperature`: leaf temperature (in ºC)
- `biophysics_leafVapourPressure`: leaf vapour pressure (in kPa)
- `biophysics_radiationDiurnalPattern`: the proportion of daily radiation corresponding to the input time in seconds after sunrise.
- `biophysics_temperatureDiurnalPattern`: diurnal pattern of temperature.
- `biophysics_waterDynamicViscosity`: Water dynamic viscosity relative to 20ºC.

`carbon` *Carbon-related functions*

---

## Description

Set of functions used in the calculation of carbon balance.

## Usage

```
carbon_leafStarchCapacity(LAI, N, SLA, leafDensity)
carbon_leafStructuralBiomass(LAI, N, SLA)
carbon_sapwoodStarchCapacity(SA, H, L, V, woodDensity, conduit2sapwood)
carbon_sapwoodStructuralBiomass(SA, H, L, V, woodDensity)
carbon_sapwoodStructuralLivingBiomass(SA, H, L, V, woodDensity, conduit2sapwood)
carbon_sugarConcentration(osmoticWP, temp, nonSugarConc)
carbon_osmoticWaterPotential(sugarConc, temp, nonSugarConc)
carbon_relativeSapViscosity(sugarConc, temp)
carbon_sugarStarchDynamicsLeaf(sugarConc, starchConc, eqSugarConc)
carbon_sugarStarchDynamicsStem(sugarConc, starchConc, eqSugarConc)
carbon_carbonCompartments(x, biomassUnits = "g_m2")
```

## Arguments

| | |
|---|---|
| `LAI` | Leaf area index. |
| `N` | Density (ind·ha-1). |
| `SLA` | Specific leaf area (mm2/mg = m2/kg). |
| `leafDensity` | Density of leaf tissue (dry weight over volume). |
| `SA` | Sapwood area (cm2). |
| `H` | Plant height (cm). |
| `L` | Coarse root length (mm) for each soil layer. |

| | |
|---|---|
| V | Proportion of fine roots in each soil layer. |
| woodDensity | Wood density (dry weight over volume). |
| conduit2sapwood | Proportion of sapwood corresponding to conducive elements (vessels or tracheids) as opposed to parenchymatic tissue. |
| osmoticWP | Osmotic water potential (MPa). |
| temp | Temperature (degrees Celsius). |
| nonSugarConc | Concentration of inorganic solutes (mol/l). |
| sugarConc | Concentration of soluble sugars (mol/l). |
| starchConc | Concentration of starch (mol/l) |
| eqSugarConc | Equilibrium concentration of soluble sugars (mol/l). |
| x | An object of class growthInput. |
| biomassUnits | A string for output biomass units, either "g_ind" (g per individual) or "g_m2" (g per square meter). |

## Value

Values returned for each function are:

- carbon_leafStarchCapacity: Capacity of storing starch in the leaf compartment (mol gluc/ind.).
- carbon_leafStructuralBiomass: Leaf structural biomass (g dry/ind.)
- carbon_sapwoodStarchCapacity: Capacity of storing starch in the sapwood compartment (mol gluc/ind.).
- carbon_sapwoodStructuralBiomass: Sapwood structural biomass (g dry/ind.)
- carbon_sapwoodStructuralLivingBiomass: Living sapwood (parenchyma) structural biomass (g dry/ind.)
- carbon_sugarConcentration: Sugar concentration (mol gluc/l)
- carbon_osmoticWaterPotential: Osmotic component of water potential (MPa)
- carbon_relativeSapViscosity: Relative viscosity of sapwood with respect to pure water.
- carbon_sugarStarchDynamicsLeaf: Rate of conversion from sugar to starch in leaf (mol gluc/l/s).
- carbon_sugarStarchDynamicsStem: Rate of conversion from sugar to starch in leaf (mol gluc/l/s).
- carbon_carbonCompartments: A data frame with the size of compartments for each plant cohort, in the specified units.

conductancefunctions *Hydraulic confuctance functions*

## Description

Set of functions used in the calculation of soil and plant hydraulic conductance.

## Usage

```
hydraulics_psi2K(psi, Psi_extract, ws = 3.0)
hydraulics_K2Psi(K, Psi_extract, ws = 3.0)
hydraulics_averagePsi(psi, v, c, d)
hydraulics_vulnerabilityCurvePlot(x, soil = NULL, type="leaf",
                                  psiVec =  seq(-0.1, -8.0, by =-0.01),
                                  relative = FALSE, speciesNames = FALSE,
                                draw = TRUE, ylim = NULL, xlab = NULL, ylab=NULL)
hydraulics_psiCrit(c, d, pCrit = 0.001)
hydraulics_vanGenuchtenConductance(psi, krhizomax, n, alpha)
hydraulics_xylemConductance(psi, kxylemmax, c, d)
hydraulics_xylemPsi(kxylem, kxylemmax, c, d)
hydraulics_correctConductanceForViscosity(kxylem, temp)
hydraulics_psi2Weibull(psi50, psi88 = NA, psi12 = NA)
```

## Arguments

| | |
|---|---|
| psi | A scalar (or a vector, depending on the function) with water potential (in MPa). |
| K | Whole-plant relative conductance (0-1). |
| Psi_extract | Soil water potential (in MPa) corresponding to 50% whole-plant relative conductance. |
| ws | Exponent of the whole-plant relative conductance Weibull function. |
| v | Proportion of fine roots within each soil layer. |
| krhizomax | Maximum rhizosphere hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| kxylemmax | Maximum xylem hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| c, d | Parameters of the Weibull function (generic xylem vulnerability curve). |
| n, alpha | Parameters of the Van Genuchten function (rhizosphere vulnerability curve). |
| kxylem | Xylem hydraulic conductance (defined as flow per surface unit and per pressure drop). |
| x | An object of class spwbInput. |
| soil | A list containing the description of the soil (see soil). |
| type | Plot type for hydraulics_vulnerabilityCurvePlot, either "leaf", "stem", "root", "rootlayer" or "rhizosphere"). |

| | |
|---|---|
| psiVec | Vector of water potential values to evaluate for the vulnerability curve. |
| relative | A flag to relativize vulnerability curves to the [0-1] interval. |
| speciesNames | A flag to indicate the use of species names instead of cohort names in plots. |
| draw | A flag to indicate whether the vulnerability curve should be drawn or just returned. |
| ylim, xlab, ylab | Graphical parameters to override function defaults. |
| pCrit | Proportion of maximum conductance considered critical for hydraulic functioning. |
| psi50, psi88, psi12 | Water potentials (in MPa) corresponding to 50%, 88% and 12% percent conductance loss. |
| temp | Temperature (in degrees Celsius). |

## Details

Details of the hydraulic model are given in a vignette. Function hydraulics_vulnerabilityCurvePlot draws a plot of the vulnerability curves for the given soil object and network properties of each plant cohort in x.

## Value

Values returned for each function are:

- hydraulics_psi2K: Whole-plant relative conductance (0-1).
- hydraulics_K2Psi: Soil water potential (in MPa) corresponding to the given whole-plant relative conductance value (inverse of hydraulics_psi2K()).
- hydraulics_averagePsi: The average water potential (in MPa) across soil layers.
- hydraulics_vanGenuchtenConductance: Rhizosphere conductance corresponding to an input water potential (soil vulnerability curve).
- hydraulics_xylemConductance: Xylem conductance (flow rate per pressure drop) corresponding to an input water potential (plant vulnerability curve).
- hydraulics_xylemPsi: Xylem water potential (in MPa) corresponding to an input xylem conductance (flow rate per pressure drop).
- hydraulics_psi2Weibull: Parameters of the Weibull vulnerability curve that goes through the supplied psi50 and psi88 values.

---

# defaultControl *Control parameters for simulation models*

---

## Description

Creates a list control parameters default values for simulations.

## Usage

```
defaultControl(transpirationMode = "Granier")
```

## Arguments

`transpirationMode`
: Transpiration model (either 'Granier' or 'Sperry'). See `spwbInput`.

## Details

The function returns a list with default parameters. Users can change those defaults that need to be set to other values and use the list as input for model functions. The relevant parameters are different for each model function.

## Value

A list, with the following options (default values in parentheses):

**General**:

- `verbose (=TRUE)`: Boolean flag to indicate console output during calculations. In function `fordyn` `verbose` is always set to FALSE.
- `fillMissingRootParams (=TRUE)`: Boolean flag to indicate that functions `spwbInput` and `growthInput` should provide estimates for Z50 and Z95 if these are lacking in the forest data. Note that if `fillMissingRootParams` is set to `FALSE` then simulations may fail if the user does not provide values for Z50 and Z95 in tree or shrub data.
- `fillMissingSpParams (=TRUE)`: Boolean flag to indicate that functions `spwbInput` and `growthInput` should provide estimates for functional parameters if these are lacking in the species parameter table `SpParams`. Note that if `fillMissingSpParams` is set to `FALSE` then simulations may fail if the user does not provide values for required parameters.
- `subdailyResults (=FALSE)`: Boolean flag to force subdaily results to be stored (as a list called 'subdaily' of `spwb_day` objects, one by simulated date) in calls to `spwb`. In function `fordyn` `subdailyResults` is always set to FALSE.

**Water balance** (functions `spwb`, `pwb` or `spwb_day`):

- `transpirationMode (="Granier")`: Transpiration model (either 'Granier' or 'Sperry'). See `spwbInput`.
- `soilFunctions (="SX")`: Soil water retention curve and conductivity functions, either 'SX' (for Saxton) or 'VG' (for Van Genuchten). If `transpirationMode = "Sperry"` then soilFunctions is set by default to `'VG'`.
- `defaultWindSpeed (= 2.5)`: Default wind speed value (in m/s) to be used when missing from data.
- `defaultCO2 (= 386)`: Default atmospheric (abovecanopy) CO2 concentration (in micromol·mol-1 = ppm). This value will be used whenever CO2 concentration is not specified in the weather input.
- `snowpack (=TRUE)`: Boolean flag to indicate the simulation of snow accumulation and melting.
- `leafPhenology (=TRUE)`: Boolean flag to indicate the simulation of leaf phenology for winter-deciduous species.
- `rockyLayerDrainage (=TRUE)`: Boolean flag to indicate the simulation of drainage from rocky layers (> 95% of rocks).
- `unlimitedSoilWater (=FALSE)`: Boolean flag to indicate the simulation of plant transpiration assuming that soil water is always at field capacity.

- `unfoldingDD` (=300): Degree-days for complete leaf unfolding after budburst has occurred.
- `rhizosphereOverlap` (="total"): A string indicating the degree of rhizosphere spatial overlap between plant cohorts:
  - "none" - no overlap (independent water pools).
  - "partial" - partial overlap determined by coarse root volume.
  - "total" - total overlap (plants extract from common soil pools).
- `verticalLayerSize` (= 100): Size of vertical layers (in cm) for the calculation of light extinction (and photosynthesis).
- `windMeasurementHeight` (=200): Height (in cm) over the canopy corresponding to wind measurements.
- `cavitationRefill` (= "total"): A string indicating how refilling of embolized conduits is done:
  - "none" - no refilling.
  - "annual" - every first day of the year.
  - "rate" - following a rate of new sapwood formation.
  - "total" - instantaneous complete refilling.

**Water balance** (functions spwb, pwb or spwb_day when `traspirationMode` = "Granier"):

- `hydraulicRedistributionFraction` (= 0.1): Fraction of plant transpiration corresponding to hydraulic redistribution.

**Water balance** (functions spwb, pwb or spwb_day when `traspirationMode` = "Sperry"):

- `ndailysteps` (= 24): Number of steps into which each day is divided for determination of stomatal conductance, transpiration and photosynthesis (24 equals 1-hour intervals).
- `nsubsteps` (= 3600): Number of substeps into which each step is divided for multi-layer canopy energy balance solving.
- `capacitance` (=FALSE): Whether the effect of plant water compartments is considered in simulations.
- `multiLayerBalance` (=FALSE): Flag to indicate multiple canopy energy balance. If FALSE, canopy is considered a single layer for energy balance.
- `taper` (= TRUE): Whether taper of xylem conduits is accounted for when calculating aboveground stem conductance from xylem conductivity.
- `maximumStemConductance` (= 10): Maximum allowed value for the stem maximum hydraulic conductance (in mmol·s-1·m-2·MPa-1). Introduced to avoid excessive hydraulic redistribution caused by species with small size (i.e. very large stem conductance).
- `klatstem` (= 0.01): Stem symplastic-apoplastic lateral conductance (in mmol·s-1·m-2·MPa-1). Only relevant when `capacitance` = TRUE.
- `klatleaf` (= 0.01): Leaf symplastic-apoplastic lateral conductance (in mmol·s-1·m-2·MPa-1). Only relevant when `capacitance` = TRUE.
- `numericParams`: A list with the following elements:
  - `maxNsteps` (= 400): Maximum number of steps in supply function.
  - `ntrial` (= 200): Number of iteration trials when finding root of equation system.
  - `psiTol` (= 0.0001): Tolerance value for water potential.
  - `ETol` (= 0.0001): Tolerance value for flow.
- `thermalCapacityLAI` (=1000000): Thermal canopy capacitance per LAI unit.

- fracLeafResistance (= NA): Fraction of plant total resistance (leaf+stem+root) that corresponds to leaves. This fraction is used if VCleaf_kmax = NA.
- fracRootResistance (= 0.40): Fraction of plant total resistance (leaf+stem+root) that corresponds to root system.
- averageFracRhizosphereResistance (=0.15): Fraction to total continuum (leaf+stem+root+rhizosphere) resistance that corresponds to rhizosphere (averaged across soil water potential values).
- boundaryLayerSize (= 2000): Size of the boundary layer (in cm) over the canopy (relevant for multi-layer canopy energy balance).
- refillMaximumRate (= 0.05): Maximum rate of daily refilling of embolized conduits as sapwood area per leaf area (in cm2·m-2·day-1).

**Forest growth** (functions growth or growth_day):

- subdailyCarbonBalance (=FALSE): Boolean flag to indicate that labile carbon balance should be conducted at sub-daily steps (applies only to transpirationMode = "Sperry").
- allowDessication (=TRUE): Boolean flag to indicate that mortality by dessication is allowed.
- allowStarvation (=TRUE): Boolean flag to indicate that mortality by starvation is allowed.
- sinkLimitation (=TRUE): Boolean flag to indicate that temperature and turgor limitations to growth are applied.
- shrubDynamics [= TRUE]: Boolean flag to allow the application of demographic processes to shrubs.
- allocationStrategy (="Al2As"): Strategy for allocation (either "Plant_kmax", for constant maximum plant conductance, or "Al2As" for constant Huber value).
- phloemConductanceFactor (= 0.2)): Factor to transform stem xylem conductance to stem phloem conductance (only for transpirationMode = "Sperry").
- nonSugarConcentration (= 0.25): Non-sugar (inorganic) solute concentration (mol·l-1) in cells.
- equilibriumOsmoticConcentration [= c(leaf = 0.8, sapwood = 0.6)]: Equilibrium osmotic concentrations (mol·l-1) for leaf and sapwood cells. The difference between leaf and sapwood values helps maintaining phloem transport. The equilibrium sugar concentration is equilibriumOsmoticConcentration - nonSugarConcentration defaults to [= c(leaf = 0.55, sapwood = 0.35)].
- minimumRelativeStarchForGrowth [= 0.50]: Default minimum concentration of storage carbon (starch), relative to the maximum storage capacity, for sapwood growth to occur, when not specified via SpParams (RSSG).
- constructionCosts [= c(leaf = 1.5, sapwood = 1.47, fineroot = 1.30)]: Default construction costs, including respiration and structural carbon, per dry weight of new tissue (g gluc · g dry -1) when not specified via SpParams (CCleaf, CCsapwood and CCfineroot).
- senescenceRates [= c(sapwood = 0.0001261398, fineroot = 0.001897231)]: Default senescence rates (day-1) for sapwood and fineroots when not specified via SpParams (SRsapwood and SRfineroot). Defaults are equivalent to 9%, 5% and 50% annual turnover for gymnosperm sapwood, angiosperm sapwood and fine roots, respectively.
- maximumRelativeGrowthRates [= c(leaf = 0.03, cambium = 0.005, sapwood = 0.002, fineroot = 0.1)]: Default maximum relative growth rates for leaves (m2 leaf ·cm-2 sapwood· day-1), tree sapwood (cm2 sapwood· cm-1 cambium · day-1), shrub sapwood (cm2

sapwood ·cm-2 sapwood· day-1) and fine roots (g dw · g dw -1 · day -1) when not specified via SpParams (`RGRleafmax`, `RGRcambiummax` , `RGRsapwoodmax` and `RGRfinerootmax`, respectively).

- `mortalityMode` [= `"density/deterministic"`]: String describing how mortality is applied. Current accepted values are combinations of "cohort" vs "density" (for whole-cohort mortality vs reduction of stem density) and "deterministic" vs. "stochastic".
- `mortalityBaselineRate` [= `0.0015`]: Default deterministic proportion or probability specifying the baseline reduction of cohort's density occurring in a year (for `mortalityMode` = `"density/deterministic"` or `"density/stochastic"`).
- `mortalityRelativeSugarThreshold` [= `0.3`]: Threshold of stem sugar concentration, in relation to the equilibrium sugar concentration, resulting in an increased mortality rate/probability whenever levels are below.
- `mortalityRWCThreshold` [= `0.3`]: Threshold of stem relative water content resulting in increased mortality rate/probability whenever levels are below.

**Forest dynamics** (function `fordyn`):

- `allowRecruitment` (=`TRUE`): Boolean flag to indicate that recruitment is allowed.
- `recruitmentMode` [= `"stochastic"`]: String describing how recruitment is applied. Current accepted values are "deterministic" or "stochastic".
- `removeEmptyCohorts` [= `TRUE`]: Boolean flag to indicate the removal of cohorts whose density is too low.
- `minimumCohortDensity` [= `1`]: Threshold of density resulting in cohort removal.
- `seedRain` [= `NULL`]: Vector of species codes whose seed rain is to be simulated. If `NULL` the species identity of seed rain is taken from species currently present in the forest stand and with minimum size (see below).
- `seedProductionTreeHeight` [= `300`]: Default minimum tree height for producing seeds (when species parameter `SeedProductionHeight` is missing).
- `seedProductionShrubHeight` [= `30`]: Default minimum shrub height for producing seeds (when species parameter `SeedProductionHeight` is missing).
- `probRecr` = [`0.05`]: Default annual probability of recruitment (when species parameter `ProbRecr` is missing).
- `minTempRecr` [= `0`]: Default threshold of minimum average temperature of the coldest month necessary for recruiting (when species parameter `MinTempRecr` is missing).
- `minMoistureRecr` [= `0.3`]: Default threshold of minimum moisture index (annual precipitation over annual ETP) necessary for recruiting (when species parameter `MinMoistureRecr` is missing).
- `minFPARRecr` [= `10`]: Default threshold of minimum fraction of PAR (in %) reaching the ground necessary for recruiting (when species parameter `MinFPARRecr` is missing).
- `recrTreeDBH` [= `1`]: Default DBH (cm) for recruited trees (when species parameter `RecrTreeDBH` is missing).
- `recrTreeDensity` [= `100`]: Default density (ind·ha-1) for recruited trees (when species parameter `RecrTreeDensity` is missing).
- `recrTreeHeight` [= `100`]: Default height (cm) for recruited trees (when species parameter `RecrTreeHeight` is missing).
- `recrShrubCover` [= `1`]: Default cover (%) for recruited shrubs (when species parameter `RecrShrubCover` is missing).

- `recrShrubHeight` [= 25]: Default height (cm) for recruited shrubs (when species parameter `RecrShrubHeight` is missing).
- `recrTreeZ50` [= 100]: Default value for Z50 (mm) in recruited trees (when species parameter `RecrZ50` is missing).
- `recrShrubZ50` [= 50]: Default value for Z50 (mm) in recruited shrubs (when species parameter `RecrZ50` is missing).
- `recrTreeZ95` [= 1000]: Default value for Z95 (mm) in recruited trees (when species parameter `RecrZ50` is missing).
- `recrShrubZ50` [= 500]: Default value for Z95 (mm) in recruited shrubs (when species parameter `RecrZ50` is missing).

`defaultManagementFunction`

*Default forest management actions*

---

## Description

Function `defaultManagementFunction` implements management actions for 'regular' and 'irregular' monospecific stands, whereas function `defaultManagementArguments` returns a list with default values for the parameters regulating management. Both functions are meant to be used in simulations with `fordyn`.

## Usage

```
defaultManagementFunction(x, args, verbose = FALSE)
defaultManagementArguments()
```

## Arguments

| | |
|---|---|
| `x` | An object of class `forest` |
| `args` | A list of arguments regulating management actions, e.g. the list returned by `defaultManagementArguments` |
| `verbose` | A boolean flag enabling console printing. |

## Details

This function implements silvicultural actions following either 'regular' or 'irregular' management models. Irregular models are implemented by executing thinning operations only, whereas regular models include a set of final cuts. Thinning occurs anytime a stand-level metric (e.g. basal area) crosses a given threshold, and different kinds of thinning operations are allowed. Unrealistic high frequency thinning can be avoided by setting a minimum number of years to happen between thinning operations. Final cuts start whenever mean DBH exceeds a given threshold, and may include different cuts separated a number of years. Planting is only allowed under regular management models, and is applied after the last final cut. Understory clearings are assumed to occur anytime there is an intervention on trees, an only a residual shrub cover is left.

*Thinning types*:

- `above`: Extract largest trees (according to DBH) until thinning objective is met.
- `below`: Extract smallest trees (according to DBH) until thinning objective is met.
- `systematic`: Extract equally from all size classes until thinning objective is met.
- `above-systematic`: Extract half the objective as systematic thinning and the other hald as above thinning.
- `below-systematic`: Extract half the objective as systematic thinning and the other hald as below thinning.
- `free string`: A string specifying the proportion of tree cuts from size classes, with size classes separated by "/" and each one composed of a number specifying the upper limit and a number indicating its proportion, separated by "-" (e.g. "10-50/40-30/60-20").

## Value

Function `defaultManagementFunction` returns a list with the following items:

- `"action"`: A string identifying the action performed (e.g. "thinning").
- `"N_tree_cut"`: A vector with the density of trees removed.
- `"Cover_shrub_cut"`: A vector with the cover of shrubs removed.
- `"planted_forest"`: An object of class `forest` with the new plant cohorts resulting from tree/shrub planting.
- `"management_args"`: A list of management arguments to be used in the next call to the management function.

Function `defaultManagementArguments` returns a list with default arguments:

- `"type"`: Management model, either 'regular' or 'irregular'.
- `"thinning"`: Kind of thinning to be applied in irregular models or in regular models before the final cuts. Options are 'below', 'above', 'systematic', 'below-systematic', 'above-systematic' or a string with the proportion of cuts to be applied to different diameter sizes (see details).
- `"thinningMetric"`: The stand-level metric used to decide whether thinning is applied, either 'BA' (basal area), 'N' (density) or 'HB' (Hart-Becking index).
- `"thinningThreshold"`: The threshold value of the stand-level metric causing the thinning decision.

- "thinningPerc": Percentage of stand's basal area to be removed in thinning operations.
- "minThinningInterval": Minimum number of years between thinning operations.
- "yearsSinceThinning": State variable to count the years since the last thinning ocurred.
- "finalMeanDBH": Mean DBH threshold to start final cuts.
- "finalPerc": String with percentages of basal area to be removed in final cuts, separated by '-' (e.g. "40-60-100").
- "finalPreviousStage": Integer state variable to store the stage of final cuts ('0' before starting final cuts).
- "finalYearsBetweenCuts": Number of years separating final cuts.
- "finalYearsToCut": State variable to count the years to be passed before new final cut is applied.
- "plantingSpecies": Species code to be planted. If missing, planting does not occur and only natural regeneration is allowed.
- "plantingDBH": Initial DBH (cm) of planted species.
- "plantingHeight": Initial height (cm) of planted species.
- "plantingDensity": Initial density (ind./ha) of the planted species.
- "understoryMaxCover": Percentage of overall shrub cover to be left after any silvicultural intervention.

# defaultSoilParams *Default soil parameters*

---

## Description

Creates a data frame with default soil physical description for model functions.

## Usage

```
defaultSoilParams(n = 4)
```

## Arguments

| | |
|---|---|
| n | An integer with the number of soil layers (between two and five). |

### Details

The function returns a data frame with default physical soil description, with soil layers in rows. Users can change those that need to be set to other values and use the list as input for function `soil`.

### Value

A data frame with layers in rows and the following columns (and default values):

- `widths (= c(300,700,1000,2000)`: Width of soil layers (in mm).
- `clay (= 25)`: Clay percentage for each layer (in %).
- `sand (= 25)`: Sand percentage for each layer (in %).
- `om (= NA)`: Organic matter percentage for each layer (in %).
- `bd (= 1.5)`: Bulk density for each layer (in g/cm3).
- `rfc (= c(20,40,60,85))`: Percentage of rock fragment content (volume basis) for each layer.

### Note

While this function is limited to five soil layers, user defined data frames can discretize soils using an unlimited number of soil layers.

defaultSoilParams(4)
```

---

## droughtStress *Drought stress indices*

---

### Description

Calculates plant drought stress indices, at different temporal scales, from simulation results.

### Usage

```
droughtStress(x, index = "NDD", freq = "years", bySpecies = FALSE, draw = TRUE)
```

## Arguments

| | |
|---|---|
| x | An object of class spwb, pwb, growth or fordyn. |
| index | A string with the index to be calculated, either "DI", "NDD", "ADS", "MDS" or "WSI" (see details). |
| freq | Frequency of stress statistics (see cut.Date). Normally, either "years" or "months" for yearly-based or monthly-based indices. |
| bySpecies | Allows aggregating output by species. |
| draw | A boolean flag to indicate that a plot should be returned. |

## Details

The currently available drought stress indices are:

- "ADS": Average of daily drought stress values for the period considered.
- "MDS": Maximum daily drought stress during the period considered.
- "DI": Drought intensity, as defined in De Cáceres et al. (2015).
- "NDD": Number of drought days, as defined in De Cáceres et al. (2015).
- "WSI": Water stress integral, as defined in Myers (1988).

## Value

A data frame with periods (e.g., years or months) in rows and plant cohorts (or species) in columns. Values are the calculated stress index. If draw=TRUE a ggplot is returned instead.

summary.spwb, waterUseEfficiency

`evaluation` *Evaluation of simulations results*

## Description

Functions to compare model predictions against observed values.

## Usage

```
evaluation_table(out, measuredData, type = "SWC", cohort = NULL,
                 temporalResolution = "day")
evaluation_stats(out, measuredData, type="SWC", cohort = NULL,
                 temporalResolution = "day")
evaluation_plot(out, measuredData, type="SWC", cohort = NULL,
                temporalResolution = "day",
                plotType = "dynamics")
evaluation_metric(out, measuredData, type="SWC", cohort=NULL,
                  temporalResolution = "day",
                  metric = "loglikelihood")
```

## Arguments

| | |
|---|---|
| `out` | An object of class `spwb`, `growth` or `pwb`. |
| `measuredData` | A data frame with observed/measured values. Dates should be in row names, whereas columns should be named according to the type of output to be evaluated (see details). |
| `type` | A string with the kind of model output to be evaluated. Accepted values are `"SWC"` (soil moisture content), `"REW"` relative extractable water, `"ETR"` (total evapotranspiration), `"SE+TR"` (modelled soil evaporation + transpiration against observed total evapotranspiration), `"E"` (transpiration per leaf area), `"LFMC"` (Live fuel moisture content), `"WP"` (plant water potentials), `"BAI"` (basal area increment), `"DI"` (diameter increment), `"DBH"` (diameter at breast height) or `"Height"` (plant height). |
| `cohort` | A string of the cohort to be compared (e.g. "T1_68"). If `NULL` results for the first cohort will be evaluated. |
| `temporalResolution` | A string to indicate the temporal resolution of the model evaluation, which can be "day", "week", "month" or "year". Observed and modelled values are aggregated temporally (using either means or sums) before comparison. |
| `plotType` | Plot type to draw, either `"dynamics"` or `"scatter"`. |
| `metric` | An evaluation metric:<br>• `"MAE"`: Mean absolute error.<br>• `"MAE.rel"`: Mean absolute error in relative terms.<br>• `"r"`: Pearson's linear correlation coefficient.<br>• `"NSE"`: Nash-Sutcliffe model efficiency coefficient. |

- "NSE.abs": Modified Nash-Sutcliffe model efficiency coefficient (L1 norm) (Legates & McCabe 1999).
- "loglikelihood": Logarithm of the likelihood of observing the data given the model predictions, assuming independent Gaussian errors.

## Details

Users should provide the appropriate columns in measuredData, depending on the type of output to be evaluated:

- "SWC" or "REW": A column named "SWC" should be present, containing soil moisture content in percent volume. When type="REW", observed values are divided by the 90% quantile, which is assumed to be the moisture content at field capacity.
- "ETR" or "SE+TR": A column named "ETR" should be present, containing stand's evapotranspiration in mm/day (or mm/week, mm/month, etc, depending on the temporal resolution). If type="ETR" observed values will be compared against modelled evapotranspiration (i.e. sum of transpiration, soil evaporation and interception loss), whereas if type= "SE+TR" observed values will be compared against the sum of transpiration and soil evaporation only.
- "E": For each plant cohort whose transpiration is to be evaluated, a column starting with "E_" and continuing with a cohort name (e.g. "E_T1_68") with transpiration in L/m2/day on a leaf area basis (or L/m2/week, L/m2/month, etc, depending on the temporal resolution).
- "LFMC": For each plant cohort whose transpiration is to be evaluated, a column starting with "FCM_" and continuing with a cohort name (e.g. "FMC_T1_68") with fuel moisture content as percent of dry weight.
- "WP": For each plant cohort whose transpiration is to be evaluated, two columns, one starting with "PD_" (for pre-dawn) and the other with "MD_" (for midday), and continuing with a cohort name (e.g. "PD_T1_68"). They should contain leaf water potential values in MPa. These are compared against sunlit water potentials.
- "BAI": For each plant cohort whose growth is to be evaluated, a column starting with "BAI_" and continuing with a cohort name (e.g. "BAI_T1_68") with basal area increment in cm2/day, cm2/week, cm2/month or cm2/year, depending on the temporal resolution.
- "DI": For each plant cohort whose growth is to be evaluated, a column starting with "DI_" and continuing with a cohort name (e.g. "DI_T1_68") with basal area increment in cm/day, cm/week, cm/month or cm/year, depending on the temporal resolution.
- "DBH": For each plant cohort whose growth is to be evaluated, a column starting with "DBH_" and continuing with a cohort name (e.g. "DBH_T1_68") with DBH values in cm.
- "Height": For each plant cohort whose growth is to be evaluated, a column starting with "Height_" and continuing with a cohort name (e.g. "Height_T1_68") with Height values in cm.

Additional columns may exist with the standard error of measured quantities. These should be named as the referred quantity, followed by "_err" (e.g. "PD_T1_68_err"), and are used to draw confidence intervals around observations.

Row names in measuredData indicate the date of measurement (in the case of days). If measurements refer to months or years, row names should also be in a "year-month-day" format, although with "01" for days and/or months (e.g. "2001-02-01" for february 2001, or "2001-01-01" for year 2001).

## Value

- Function `evaluation_table` returns a data frame with dates, observed and predicted values.
- Function `evaluation_stats` returns evaluation statistics (a vector or a data frame depending on `type`):
  - `Bias`: Mean deviation (positive values correspond to model overestimations).
  - `Bias.rel`: Bias in relative terms (%).
  - `MAE`: Mean absolute error.
  - `MAE.rel`: Mean absolute error in relative terms (%).
  - `r`: Pearson's linear correlation coefficient.
  - `NSE`: Nash-Sutcliffe model efficiency coefficient.
  - `NSE.abs`: Modified Nash-Sutcliffe model efficiency coefficient (L1 norm) (Legates & McCabe 1999).
- Function `evaluation_plot` returns a ggplot object.
- Function `evaluation_metric` returns a scalar with the desired metric.

`exampleforest` *Example forest stands*

---

## Description

Data set for illustration of model behaviour. Includes a description of the plant cohorts of a forest stand.

## Usage

```
data(exampleforestMED)
data(exampleforestUS)
```

## Format

An object of class `forest` containing the description of the tree, sapling and shrub cohorts of a forest patch.

## Source

DGCN (2005). Tercer Inventario Forestal Nacional (1997-2007): Catalunya. Dirección General de Conservación de la Naturaleza, Ministerio de Medio Ambiente, Madrid.

examplemeteo *Example daily meteorology data*

## Description

Example data set of meteorological input.

## Usage

```
data(examplemeteo)
```

## Format

A data frame containing daily meteorology of a location in Catalonia (Spain) for year 2001.

`MinTemperature` Minimum daily temperature (in degrees Celsius).

`MaxTemperature` Maximum daily temperature (in degrees Celsius).

`Precipitation` Daily precipitation (in mm of water).

`MinRelativeHumidity` Minimum daily relative humidity (in percent).

`MaxRelativeHumidity` Maximum daily relative humidity (in percent).

`Radiation` Incoming radiation (in MJ/m2).

`WindSpeed` Wind speed (in m/s).

## Source

Interpolated from weather station data (Spanish and Catalan meteorology agencies) using package 'meteoland'.

## See Also

spwb

## Examples

```
data(examplemeteo)
```

`exampleobs` *Example observed data*

## Description

Example (fake) data set of variables measured in a plot.

## Usage

```
data(exampleobs)
```

## Format

A data frame containing daily 'observed' values for year 2001.

`SWC` Soil moisture content (in m3/m3).

`ETR` Total evapotranspiration (mm).

`E_T1_148` Transpiration of Pinus halepensis cohort 'T1_148' (L/m2 of leaf area).

`E_T2_168` Transpiration of Quercus ilex cohort 'T2_168' (L/m2 of leaf area).

`FMC_T1_148` Fuel moisture content of Pinus halepensis cohort 'T1_148' (in percent).

`FMC_T2_168` Fuel moisture content of Quercus ilex cohort 'T2_168' (in percent).

`BAI_T1_148` Basal area increment for Pinus halepensis cohort 'T1_148' (in cm2).

`BAI_T2_168` Basal area increment for Quercus ilex cohort 'T2_168' (in cm2).

`DI_T1_148` Diameter increment for Pinus halepensis cohort 'T1_148' (in cm).

`DI_T2_168` Diameter increment for Quercus ilex cohort 'T2_168' (in cm).

## Source

This data set was actually created by running a simulation and adding some gaussian error to the outputs.

## See Also

```

`extractSubdaily` *Extracts subdaily output*

## Description

Given the result of simulations, this function extracts subdaily output corresponding to each simulated day and returns it as a data frame.

## Usage

```
extractSubdaily(x, output = "E", dates = NULL)
```

## Arguments

| | |
|---|---|
| `x` | An object returned by simulation functions `spwb`, `pwb` or `growth`. |
| `output` | See options in section details. |
| `dates` | A date vector indicating the subset of simulated days for which subdaily output is desired. |

## Details

This function only works when simulations have been carried using control option 'subdailyResults = TRUE' (see `defaultControl`). Subdaily simulation results will then be stored as elements of the a list called 'subdaily' in the simulation output. Function `extractSubdaily` will assemble subdaily results from this list and return them as a data frame. Options for parameter 'output' are the following:

- Functions pwb() and spwb(): "E","Ag","An","dEdP","RootPsi","StemPsi","LeafPsi","StemPLC","StemRWC","LeafRW "Temperature", "ExtractionInst".
- Additional options for shade and sunlit leaves in pwb() and spbw(): Either "SunlitLeaves$x" or "ShadeLeaves$x" where 'x' is one of the following: "Abs_SWR","Net_LWR","E","Ag","An","Ci","Gsw","VPD","Tem
- Additional options for function growth(): "GrossPhotosynthesis", "MaintenanceRespiration", "GrowthCosts", "LabileCarbonBalance","SugarLeaf", "SugarSapwood", "StarchLeaf", "StarchSapwood","SugarTransport".

## Value

A data frame with a column 'datetime' and as many columns as plant cohorts.

`summary.spwb`

`fireHazard` *Fire hazard*

## Description

Estimates potential fire behaviour at each daily step of a simulation

## Usage

```
fireHazard(x, SpParams, forest = NULL, standardConditions = FALSE,
           freq="days", fun = "max")
```

## Arguments

| | |
|---|---|
| `x` | An object of class `spwb`, `spwb_day`, `pwb`, `growth`, `growth_day` or `fordyn`. |
| `SpParams` | A data frame with species parameters (see `SpParamsDefinition` and `SpParamsMED`). |
| `forest` | An object of class `forest` (needed if `x` is not of class `fordyn`). |
| `standardConditions` | A flag to indicate that standard fire weather conditions are to be used (instead of deriving fuel moisture and windspeed from `x`). |
| `freq` | Frequency of summary statistics (see `cut.Date`). |
| `fun` | Summary function (by default, maximum values). |

## Details

Live fuel moisture of shrub and canopy layers is estimated from plant water status. Dead fuel moisture is estimated following Resco-de-Dios et al. (2015).

## Value

A matrix with fire behaviour variables (columns) for each simulated day (rows) or coarser time steps if summaries are requested.

---

# fire_behaviour *Fire behaviour functions*

---

## Description

Function `fire_FCCS()` implements a modification of the fire behavior models described for the Fuel Characteristics Classification System (FCCS) in Prichard et al. (2013). Function `fire_Rothermel()` implements Rothermel's (1972) fire behaviour model (modified from package 'Rothermel' (Giorgio Vacchiano, Davide Ascoli)).

## Usage

```
fire_FCCS(FCCSpropsSI, MliveSI = as.numeric(c(90, 90, 60)),
          MdeadSI = as.numeric(c(6, 6, 6, 6, 6)),
          slope = 0, windSpeedSI = 11)
fire_Rothermel(modeltype, wSI, sSI, delta, mx_dead,
               hSI, mSI, u, windDir, slope, aspect)
```

## Arguments

| | |
|---|---|
| FCCSpropsSI | A data frame describing the properties of five fuel strata (canopy, shrub, herbs, dead woody and litter) returned by fuel_FCCS. |
| MliveSI | Moisture of live fuels (in percent of dry weight) for canopy, shrub, and herb strata. Live moisture values are drawn from column ActFCM in FCCSpropsSI if available (see fuel_FCCS). Otherwise, moisture values supplied for MliveSI are used. |
| MdeadSI | Moisture of dead fuels (in percent of dry weight) for canopy, shrub, herb, woody and litter strata. |
| slope | Slope (in degrees). |
| windSpeedSI | Wind speed (in m/s) at 20 ft (6 m) over vegetation (default 11 m/s = 40 km/h) |
| modeltype | 'S'(tatic) or 'D'(ynamic) |
| wSI | A vector of fuel load (t/ha) for five fuel classes. |
| sSI | A vector of surface-to-volume ratio (m2/m3) for five fuel classes. |
| delta | A value of fuel bed depth (cm). |
| mx_dead | A value of dead fuel moisture of extinction (percent). |
| hSI | A vector of heat content (kJ/kg) for five fuel classes. |
| mSI | A vector of percent moisture on a dry weight basis (percent) for five fuel classes. |
| u | A value of windspeed (m/s) at midflame height. |
| windDir | Wind direction (in degrees from north). North means blowing from north to south. |
| aspect | Aspect (in degrees from north). |

## Details

Default moisture, slope and windspeed values are benchmark conditions used to calculate fire potentials (Sandberg et al. 2007) and map vulnerability to fire.

## Value

Both functions return list with fire behavior variables. In the case of fire_FCCS, the function returns the variables in three blocks (lists SurfaceFire, CrownFire and FirePotentials), and the values are:

- SurfaceFire$`midflame_WindSpeed [m/s]`: Midflame wind speed in the surface fire.
- SurfaceFire$phi_wind: Spread rate modifier due to wind.
- SurfaceFire$phi_slope: Spread rate modifier due to slope.
- SurfaceFire$`I_R_surf [kJ/m2/min]`: Intensity of the surface fire reaction.
- SurfaceFire$`I_R_litter [kJ/m2/min]`: Intensity of the litter fire reaction.
- SurfaceFire$`q_surf [kJ/m2]`: Heat sink of the surface fire.
- SurfaceFire$`q_litter [kJ/m2]`: Heat sink of the litter fire.
- SurfaceFire$xi_surf: Propagating flux ratio of the surface fire.

- SurfaceFire$xi_litter: Propagating flux ratio of the litter fire.
- SurfaceFire$`ROS_surf [m/min]`: Spread rate of the surface fire(without accounting for faster spread in the litter layer).
- SurfaceFire$`ROS_litter [m/min]`: Spread rate of the litter fire.
- SurfaceFire$`ROS_windslopecap [m/min]`: Maximum surface fire spread rate according to wind speed.
- SurfaceFire$`ROS [m/min]`: Final spread rate of the surface fire.
- SurfaceFire$`I_b [kW/m]`: Fireline intensity of the surface fire.
- SurfaceFire$`FL [m]`: Flame length of the surface fire.
- CrownFire$`I_R_canopy [kJ/m2/min]`: Intensity of the canopy fire reaction.
- CrownFire$`I_R_crown [kJ/m2/min]`: Intensity of the crown fire reaction (adding surface and canopy reactions).
- CrownFire$`q_canopy [kJ/m2]`: Heat sink of the canopy fire.
- CrownFire$`q_crown [kJ/m2]`: Heat sink of the crown fire (adding surface and canopy heat sinks).
- CrownFire$xi_surf: Propagating flux ratio of the crown fire.
- CrownFire$`canopy_WindSpeed [m/s]`: Wind speed in the canopy fire (canopy top wind speed).
- CrownFire$WAF: Wind speed adjustment factor for crown fires.
- CrownFire$`ROS [m/min]`: Spread rate of the crown fire.
- CrownFire$Ic_ratio: Crown initiation ratio.
- CrownFire$`I_b [kW/m]`: Fireline intensity of the crown fire.
- CrownFire$`FL [m]`: Flame length of the crown fire.
- FirePotentials$RP: Surface fire reaction potential ([0-9]).
- FirePotentials$SP: Surface fire spread rate potential ([0-9]).
- FirePotentials$FP: Surface fire flame length potential ([0-9]).
- FirePotentials$SFP: Surface fire potential ([0-9]).
- FirePotentials$IC: Crown initiation potential ([0-9]).
- FirePotentials$TC: Crown-to-crown transmission potential ([0-9]).
- FirePotentials$RC: Crown fire spread rate potential ([0-9]).
- FirePotentials$CFC: Crown fire potential ([0-9]).

## Note

Default moisture, slope and windspeed values are benchmark conditions used to calculate fire potentials (Sandberg et al. 2007) and map vulnerability to fire.

                    mx_dead = as.numeric(SFM_metric["A6",13]),
                    hSI = as.numeric(SFM_metric["A6",14:18]),
                    mSI = c(10,10,10,30,60),
                    u=umf, windDir=0, slope=0, aspect=0)
```

fordyn *Forest dynamics*

## Description

Function fordyn implements a forest dynamics model that simulates growth, mortality, recruitment and (optionally) management actions in a given forest stand during a period specified in the input climatic data.

## Usage

```
fordyn(forest, soil, SpParams, meteo, control,
       latitude , elevation = NA, slope = NA, aspect = NA,
       CO2ByYear = numeric(0),
       management_function = NULL, management_args = NULL)
```

## Arguments

| | |
|---|---|
| forest | An object of class forest. Alternatively, the output of a previous run, if continuing a previous simulation. |
| soil | An object of class soil. |
| SpParams | A data frame with species parameters (see SpParamsMED and SpParamsDefinition). |
| meteo | A data frame with daily meteorological data series. Row names of the data frame should correspond to date strings with format "yyyy-mm-dd" (see Date). |
| control | A list with default control parameters (see defaultControl). |
| latitude | Latitude (in degrees). Required when x$TranspirationMode = "Sperry". |
| elevation, slope, aspect | Elevation above sea level (in m), slope (in degrees) and aspect (in degrees from North). Required when x$TranspirationMode = "Sperry". Elevation is also required for 'Granier' if snowpack dynamics are simulated. |
| CO2ByYear | A named numeric vector with years as names and atmospheric CO2 concentration (in ppm) as values. Used to specify annual changes in CO2 concentration along the simulation (as an alternative to specifying daily values in meteo). |
| management_function | A function that implements forest management actions (see details). |
| management_args | A list of additional arguments to be passed to the management_function. |

## Details

Function fordyn simulates forest dynamics for annual time steps, building on other simulation functions. For each simulated year, the function performs the following steps:

1. Calls function growth to simulate daily water/carbon balance, growth and mortality processes and update the forest object.

2. If required, calls function `management_function`, using as parameters the forest object and `management_args`, which may result in a density reduction for existing plant cohorts and/or a set of new planted cohorts.
3. Simulate natural recruitment (for species present in the stand or given in a seed rain input).
4. Prepares the input of function `growth` for the next annual time step.
5. Store forest status, management arguments, and summaries.

To enable forest management, the user needs to provide a function that implements it, which is passed to `fordyn` via its argument `management_function`. Such function should have the following arguments:

- `"x"`: the `forest` object representing the stand to be managed.
- `"args"`: a list of parameters regulating the behavior of the management function.
- `"verbose"`: a logical flag to enable console output during the execution of the management function.

and return a list with the following elements:

- `"action"`: A string identifying the action performed (e.g. "thinning").
- `"N_tree_cut"`: A vector with the density of trees removed.
- `"Cover_shrub_cut"`: A vector with the cover of shrubs removed.
- `"planted_forest"`: An object of class `forest` with the new plant cohorts resulting from tree/shrub planting.
- `"management_args"`: A list of management arguments to be used in the next call to the management function.

An example of management function is provided in `defaultManagementFunction`.

## Value

A list of class 'fordyn' with the following elements:

- `"StandSummary"`: A data frame with stand-level summaries (tree basal area, tree density, shrub cover, etc.) at the beginning of the simulation and after each simulated year.
- `"SpeciesSummary"`: A data frame with species-level summaries (tree basal area, tree density, shrub cover, etc.) at the beginning of the simulation and after each simulated year.
- `"CohortSummary"`: A data frame with cohort-level summaries (tree basal area, tree density, shrub cover, etc.) at the beginning of the simulation and after each simulated year.
- `"TreeTable"`: A data frame with tree-cohort data (species, density, diameter, height, etc.) at the beginning of the simulation (if any) and after each simulated year.
- `"DeadTreeTable"`: A data frame with dead tree-cohort data (species, density, diameter, height, etc.) at the beginning of the simulation and after each simulated year.
- `"CutTreeTable"`: A data frame with cut tree data (species, density, diameter, height, etc.) after each simulated year.
- `"ShrubTable"`: A data frame with shrub-cohort data (species, density, cover, height, etc.) at the beginning of the simulation and after each simulated year.

- "DeadShrubTable": A data frame with dead shrub-cohort data (species, density, cover, height, etc.) at the beginning of the simulation (if any) and after each simulated year.
- "CutShrubTable": A data frame with cut shrub data (species, density, cover, height, etc.) after each simulated year.
- "ForestStructures": A list with the forest object of the stand at the beginning of the simulation and after each simulated year.
- "GrowthResults": A list with the results of calling function growth for each simulated year.
- "ManagementArgs": A list of management arguments to be used in another call to fordyn.
- "NextInputObject": An object of class growthInput to be used in a subsequent simulation.
- "NextForestObject": An object of class forest to be used in a subsequent simulation.

---

`forest` *Forest description*

---

## Description

Description of a forest stand.

## Usage

```
## S3 method for class 'forest'
summary(object, SpParams, mode = "MED", detailed=FALSE, ...)
## S3 method for class 'summary.forest'
print(x, digits = getOption("digits"), ...)
emptyforest(ID="", patchsize=10000, ntree = 0, nshrub = 0)
```

## Arguments

`object` An object of class `forest` has the following structure:

- `ID`: An identifier of the forest stand (a string).
- `patchsize`: The area that forest stand description represents, in square meters.
- `treeData`: A data frame of tree cohorts (in rows) and the following columns:
  - `Species`: Non-negative integer for tree species identity (i.e., 0,1,2,...).
  - `Height`: Total height (in cm).
  - `DBH`: Diameter at breast height (in cm).
  - `N`: Density (number of individuals/cell).
  - `Z50`: Depth (in mm) corresponding to 50% of fine roots.
  - `Z95`: Depth (in mm) corresponding to 95% of fine roots.
- `shrubData`: A data frame of shrub cohorts (in rows) and the following columns:
  - `Species`: Non-negative integer for shrub species identity (i.e., 0,1,2,...).
  - `Height`: Total height (in cm).
  - `Cover`: Percent cover.
  - `Z50`: Depth (in mm) corresponding to 50% of fine roots.

  - Z95: Depth (in mm) corresponding to 95% of fine roots.
- seedBank: A data frame containing the abundance of seeds for each species (in rows) and the following columns:
  - Species: Non-negative integer for shrub species identity (i.e., 0,1,2,...).
  - Abundance: Abundance class (0 - none; 1 - low; 2 - medium; 3 - high; 4 - very high).
- herbCover: Percent cover of the herb layer.
- herbHeight: Mean height (in cm) of the herb layer.

| | |
|---|---|
| SpParams | A data frame with species parameters (see SpParamsMED). |
| mode | Calculation mode, either "MED" or "US". |
| detailed | A boolean flag to indicate that a detailed summary is desired. |
| x | The object returned by summary.forest. |
| digits | Minimal number of significant digits. |
| ... | Additional parameters for functions summary and print. |
| ID | An identifier of the forest stand (a string). |
| patchsize | The area of the forest stand, in square meters. |
| ntree, nshrub | Number of tree and shrub cohorts, respectively. |

## Details

Function summary.forest can be used to summarize a forest object in the console. Function emptyforest creates an empty forest object.

## Value

Function summary.forest returns a list with several structural attributes, such as the basal area and LAI of the forest. Function emptyforest returns an empty forest object.

## Forest manipulation *Forest utility functions*

### Description

Functions to manipulate a forest object.

### Usage

```
forest_mergeTrees(x, byDBHclass = TRUE)
forest_mergeShrubs(x, byHeightclass = TRUE)
```

### Arguments

| | |
|---|---|
| x | An object of class forest. |
| byDBHclass | Boolean flag to indicate that 5-cm tree DBH classes should be kept separated. |
| byHeightclass | Boolean flag to indicate that 10-cm shrub height classes should be kept separated. |

### Value

Another forest object with merged trees or shrubs, depending on the function.

## fuel_properties *Fuel stratification and fuel characteristics*

### Description

Function fuel_stratification provides a stratification of the stand into understory and canopy strata. Function fuel_FCCS calculates fuel characteristics from a forest object following an adaptation of the protocols described for the Fuel Characteristics Classification System (Prichard et al. 2013). Function fuel_windAdjustmentFactor determines the adjustment factor of wind for surface fires, according to Andrews (2012).

## Usage

```
fuel_stratification(object, SpParams, gdd = NA, mode = "MED",
                    heightProfileStep = 10.0, maxHeightProfile = 5000.0,
                    bulkDensityThreshold = 0.05)
fuel_FCCS(object, SpParams, cohortFMC = as.numeric(c()),
        gdd = NA, mode = "MED", heightProfileStep = 10, maxHeightProfile = 5000,
          bulkDensityThreshold = 0.05, depthMode = "crownaverage")
fuel_windAdjustmentFactor(topShrubHeight, bottomCanopyHeight, topCanopyHeight,
                          canopyCover)
```

## Arguments

| | |
|---|---|
| `object` | An object of class `forest` |
| `SpParams` | A data frame with species parameters (see `SpParamsMED`). |
| `cohortFMC` | A numeric vector of (actual) fuel moisture content by cohort. |
| `gdd` | Growth degree-days. |
| `mode` | Calculation mode, either "MED" or "US". |
| `heightProfileStep` | Precision for the fuel bulk density profile. |
| `maxHeightProfile` | Maximum height for the fuel bulk density profile. |
| `bulkDensityThreshold` | Minimum fuel bulk density to delimit fuel strata. |
| `depthMode` | Specifies how fuel depth (and therefore canopy and understory bulk density) should be estimated:<br>• `"crownaverage"`: As weighed average of crown lengths using loadings as weights.<br>• `"profile"`: As the difference of base and top heights in bulk density profiles.<br>• `"absoluteprofile"`: As the difference of absolute base and absolute top heights in bulk density profiles. |
| `topShrubHeight` | Shrub stratum top height (in m). |
| `bottomCanopyHeight` | Canopy base height (in m). |
| `topCanopyHeight` | Canopy top height (in m). |
| `canopyCover` | Canopy percent cover. |

## Details

Details are described in a vignette.

## Value

Function `fuel_FCCS` returns a data frame with five rows corresponding to fuel layers: `canopy`, `shrub`, `herb`, `woody` and `litter`. Columns correspond fuel properties:

- `w`: Fine fuel loading (in kg/m2).
- `cover`: Percent cover.
- `hbc`: Height to base of crowns (in m).
- `htc`: Height to top of crowns (in m).
- `delta`: Fuel depth (in m).
- `rhob`: Fuel bulk density (in kg/m3).
- `rhop`: Fuel particle density (in kg/m3).
- `PV`: Particle volume (in m3/m2).
- `beta`: Packing ratio (unitless).
- `betarel`: Relative packing ratio (unitless).
- `etabetarel`: Reaction efficiency (unitless).
- `sigma`: Surface area-to-volume ratio (m2/m3).
- `pDead`: Proportion of dead fuels.
- `FAI`: Fuel area index (unitless).
- `h`: High heat content (in kJ/kg).
- `RV`: Reactive volume (in m3/m2).
- `MinFMC`: Minimum fuel moisture content (as percent over dry weight).
- `MaxFMC`: Maximum fuel moisture content (as percent over dry weight).
- `ActFMC`: Actual fuel moisture content (as percent over dry weight). These are set to `NA` if parameter `cohortFMC` is empty.

Function `fuel_stratification` returns a list with the following items:

- `surfaceLayerBaseHeight`: Base height of crowns of shrubs in the surface layer (in cm).
- `surfaceLayerTopHeight`: Top height of crowns of shrubs in the surface layer (in cm).
- `understoryLAI`: Cumulated LAI of the understory layer (i.e. leaf area comprised between surface layer base and top heights).
- `canopyBaseHeight`: Base height of tree crowns in the canopy (in cm).
- `canopyTopHeight`: Top height of tree crowns in the canopy (in cm).
- `canopyLAI`: Cumulated LAI of the canopy (i.e. leaf area comprised between canopy base and top heights).

Function `fuel_cohortFineFMC` returns a list with three matrices (for leaves, twigs and fine fuels). Each of them contains live moisture content values for each day (in rows) and plant cohort (in columns).

Function `fuel_windAdjustmentFactor` returns a value between 0 and 1.

## growth *Forest growth*

---

### Description

Function growth is a process-based model that performs energy, water and carbon balances; and determines changes in water/carbon pools, functional variables (leaf area, sapwood area, root area) and structural ones (tree diameter, tree height, shrub cover) for woody plant cohorts in a given forest stand during a period specified in the input climatic data.

### Usage

```
growth(x, meteo,  latitude,
       elevation = NA, slope = NA, aspect = NA,
       CO2ByYear = numeric(0))
```

## Arguments

| | |
|---|---|
| x | An object of class growthInput. |
| meteo | A data frame with daily meteorological data series. Row names of the data frame should correspond to date strings with format "yyyy-mm-dd" (see Date).The following columns are required:<br>• MinTemperature: Minimum temperature (in degrees Celsius).<br>• MaxTemperature: Maximum temperature (in degrees Celsius).<br>• MinRelativeHumidity: Minimum relative humidity (in percent).<br>• MaxRelativeHumidity: Maximum relative humidity (in percent).<br>• Precipitation: Precipitation (in mm).<br>• Radiation: Solar radiation (in MJ/m2/day), required only if snowpack = TRUE.<br>• WindSpeed: Wind speed (in m/s). If not available, this column can be left with NA values.<br>• CO2: Atmospheric (abovecanopy) CO2 concentration (in ppm). This column may not exist, or can be left with NA values. In both cases simulations will assume a constant value specified in defaultControl. |
| latitude | Latitude (in degrees). Required when x$TranspirationMode = "Sperry". |
| elevation, slope, aspect | Elevation above sea level (in m), slope (in degrees) and aspect (in degrees from North). Required when x$TranspirationMode = "Sperry". Elevation is also required for 'Granier' if snowpack dynamics are simulated. |
| CO2ByYear | A named numeric vector with years as names and atmospheric CO2 concentration (in ppm) as values. Used to specify annual changes in CO2 concentration along the simulation (as an alternative to specifying daily values in meteo). |

## Details

Detailed model description is available in the vignettes section. Simulations using the 'Sperry' transpiration mode are computationally much more expensive than those using the simple transpiration mode.

## Value

A list of class 'growth' with the following elements:

- "latitude": Latitude (in degrees) given as input.
- "topography": Vector with elevation, slope and aspect given as input.
- "weather": A copy of the input weather data frame.
- "growthInput": A copy of the object x of class growthInput given as input.
- "growthOutput": An copy of the final state of the object x of class growthInput.
- "WaterBalance": A data frame where different water balance variables (see spwb).
- "EnergyBalance": A data frame with the daily values of energy balance components for the soil and the canopy (only for transpirationMode = "Sperry"; see spwb).

- "CarbonBalance": A data frame where different stand-level carbon balance components (gross primary production, maintenance respiration, synthesis respiration and net primary production), all in g C · m-2.
- "BiomassBalance": A data frame with the daily values of stand biomass balance components (in g dry · m-2.
- "Temperature": A data frame with the daily values of minimum/mean/maximum temperatures for the atmosphere (input), canopy and soil (only for transpirationMode = "Sperry"; see spwb).
- "Soil": A data frame where different soil variables (see spwb).
- "Stand": A data frame where different stand-level variables (see spwb).
- "Plants": A list of daily results for plant cohorts (see spwb).
- "SunlitLeaves" and "ShadeLeaves": A list with daily results for sunlit and shade leaves (only for transpirationMode = "Sperry"; see spwb).
- "LabileCarbonBalance": A list of daily labile carbon balance results for plant cohorts, with elements:
  - "GrossPhotosynthesis": Daily gross photosynthesis per dry weight of living biomass (g gluc · g dry-1).
  - "MaintentanceRespiration": Daily maintenance respiration per dry weight of living biomass (g gluc · g dry-1).
  - "GrowthCosts": Daily growth costs per dry weight of living biomass (g gluc · g dry-1).
  - "RootExudation": Root exudation per dry weight of living biomass (g gluc · g dry-1).
  - "LabileCarbonBalance": Daily labile carbon balance (photosynthesis - maintenance respiration - growth costs - root exudation) per dry weight of living biomass (g gluc · g dry-1).
  - "SugarLeaf": Sugar concentration (mol·l-1) in leaves.
  - "StarchLeaf": Starch concentration (mol·l-1) in leaves.
  - "SugarSapwood": Sugar concentration (mol·l-1) in sapwood.
  - "StarchSapwood": Starch concentration (mol·l-1) in sapwood.
  - "SugarTransport": Average instantaneous rate of carbon transferred between leaves and stem compartments via floem (mol gluc·s-1).
- "PlantBiomassBalance": A list of daily plant biomass balance results for plant cohorts, with elements:
  - "StructuralBiomassBalance": Daily structural biomass balance (g dry · m-2).
  - "LabileBiomassBalance": Daily labile biomass balance (g dry · m-2).
  - "PlantBiomassBalance": Daily plant biomass balance, i.e. labile change + structural change (g dry · m-2).
  - "MortalityBiomassLoss": Biomass loss due to mortality (g dry · m-2).
  - "CohortBiomassBalance": Daily cohort biomass balance (including mortality) (g dry · m-2).
- "PlantStructure": A list of daily area and biomass values for compartments of plant cohorts, with elements:
  - "LeafBiomass": Daily amount of leaf structural biomass (in g dry) for an average individual of each plant cohort.

  - "SapwoodBiomass": Daily amount of sapwood structural biomass (in g dry) for an average individual of each plant cohort.
  - "FineRootBiomass": Daily amount of fine root biomass (in g dry) for an average individual of each plant cohort.
  - "LeafArea": Daily amount of leaf area (in m2) for an average individual of each plant cohort.
  - "SapwoodArea": Daily amount of sapwood area (in cm2) for an average individual of each plant cohort.
  - "FineRootArea": Daily amount of fine root area (in m2) for an average individual of each plant cohort.
  - "HuberValue": The ratio of sapwood area to (target) leaf area (in cm2/m2).
  - "RootAreaLeafArea": The ratio of fine root area to (target) leaf area (in m2/m2).
  - "DBH": Diameter at breast height (in cm) for an average individual of each plant cohort.
  - "Height": Height (in cm) for an average individual of each plant cohort.
- "GrowthMortality": A list of daily growth and mortality rates for plant cohorts, with elements:
  - "LAgrowth": Leaf area growth (in m2·day-1) for an average individual of each plant cohort.
  - "SAgrowth": Sapwood area growth rate (in cm2·day-1) for an average individual of each plant cohort.
  - "FRAgrowth": Fine root area growth (in m2·day-1) for an average individual of each plant cohort.
  - "StarvationRate": Daily mortality rate from starvation (ind/d-1).
  - "DessicationRate": Daily mortality rate from dessication (ind/d-1).
  - "MortalityRate": Daily mortality rate (any cause) (ind/d-1).
- "subdaily": A list of objects of class growth_day, one per day simulated (only if required in control parameters, see defaultControl).

---

`hydrology_rainInterception` *Rainfall interception*

---

## Description

Function `hydrology_rainInterception` calculates the amount of rainfall intercepted daily by the canopy, given a rainfall and canopy characteristics. Two canopy interception models are currently available: the sparse Gash (1995) model and the Liu (2001) model. In both cases the current implementation assumes no trunk interception.

## Usage

```
hydrology_rainInterception(Rainfall, Cm, p, ER=0.05, method="Gash1995")
hydrology_erFactor(doy, pet, prec, Rconv = 5.6, Rsyn = 1.5)
hydrology_interceptionPlot(x, SpParams, ER = 0.05, gdd = NA, throughfall = FALSE)
```

## Arguments

| | |
|---|---|
| `Rainfall` | A numeric vector of (daily) rainfall. |
| `Cm` | Canopy water storage capacity. |
| `p` | Proportion of throughfall (normally 1 - c, where c is the canopy cover). |
| `ER` | The ratio of evaporation rate to rainfall rate. |
| `method` | Rainfall interception method (either `"Gash1995"` or `"Liu2001"`). |

| | |
|---|---|
| doy | Day of the year. |
| pet | Potential evapotranspiration for a given day (mm). |
| prec | Precipitation for a given day (mm). |
| Rconv, Rsyn | Rainfall rate for convective storms and synoptic storms, respectively, in mm/h. |
| x | An object of class spwbInput. |
| SpParams | A data frame with species parameters (see SpParamsMED and SpParamsMED). |
| gdd | Growth degree days (in Celsius). |
| throughfall | Boolean flag to plot relative throughfall instead of percentage of intercepted rainfall. |

## Details

Function hydrology_rainInterception can accept either vectors or scalars as parameters Cm, p and ER. If they are supplied as vectors they should be of the same length as Rainfall.

Function hydrology_erFactor calculates the evaporation-to-rainfall ratio for input values of potential evapotranspiration and rainfall, while accounting for seasonal variation in rainfall intensity (mm/h). Default values Rconv = 5.6 and Rsyn = 1.5 come from Miralles et al. (2010).

## Value

Function hydrology_rainInterception returns a vector of the same length as Rainfall containing intercepted rain values. Function hydrology_erFactor returns a scalar with the evaporation-to-rainfall ratio.

# hydrology_soilWaterInputs

*Soil water processes*

---

## Description

High-level functions for hydrological processes. Function `hydrology_soilWaterInputs` performs canopy water interception and snow accumulation/melt. Function `hydrology_soilInfiltrationPercolation` performs soil infiltration and percolation from the input given by the previous function.

## Usage

```
hydrology_soilWaterInputs(soil, soilFunctions, prec, er, tday, rad,
                          elevation, Cm, LgroundPAR, LgroundSWR, runon = 0,
                          snowpack = TRUE, modifySoil = TRUE)
hydrology_soilInfiltrationPercolation(soil, soilFunctions, waterInput,
                                      rockyLayerDrainage = TRUE, modifySoil = TRUE)
```

## Arguments

| | |
|---|---|
| `soil` | A list containing the description of the soil (see `soil`). |
| `soilFunctions` | Soil water retention curve and conductivity functions, either 'SX' (for Saxton) or 'VG' (for Van Genuchten). |
| `prec` | Precipitation for a given day (mm) |
| `waterInput` | Soil water input for a given day (mm). |
| `er` | The ratio of evaporation rate to rainfall rate. |
| `tday` | Average day temperature (ºC). |
| `rad` | Solar radiation (in MJ/m2/day). |
| `elevation` | Altitude above sea level (m). |
| `Cm` | Canopy water storage capacity. |
| `LgroundPAR` | Percentage of photosynthetically-acvive radiation (PAR) reaching the ground. |
| `LgroundSWR` | Percentage of short-wave radiation (SWR) reaching the ground. |
| `runon` | Surface water amount running on the target area from upslope (in mm). |

| | |
|---|---|
| snowpack | Boolean flag to indicate the simulation of snow accumulation and melting. |
| rockyLayerDrainage | Boolean flag to indicate the simulation of drainage from rocky layers (> 95% of rocks). |
| modifySoil | Boolean flag to indicate that the input soil object should be modified during the simulation. |

## Details

The function simulates different vertical hydrological processes, which are described separately in other functions. If modifySoil = TRUE the function will modify the soil object (including both soil moisture and the snowpack on its surface) as a result of simulating hydrological processes.

## Value

Function hydrology_soilWaterInputs returns a named vector with the following elements, all in mm:

| | |
|---|---|
| Rain | Precipitation as rainfall. |
| Snow | Precipitation as snow. |
| Interception | Rainfall water intercepted by the canopy and evaporated. |
| NetRain | Rainfall reaching the ground. |
| Snowmelt | Snow melted during the day, and added to the water infiltrated. |
| Runon | Surface water amount running on the target area from upslope. |
| Input | Total soil input, including runon, snowmelt and net rain. |

Function hydrology_soilInfiltrationPercolation returns a named vector with the following elements, all in mm:

| | |
|---|---|
| Infiltration | Water infiltrated into the soil (i.e. throughfall + runon + snowmelt - runoff). |
| Runoff | Surface water leaving the target area. |
| DeepDrainage | Water leaving the target soil towards the water table. |

light *Radiation transfer functions*

## Description

Functions `light_layerIrradianceFraction` and `light_layerIrradianceFractionBottomUp` calculate the fraction of above-canopy irradiance (and the soil irradiance, respectively) reaching each vegetation layer. Function `light_layerSunlitFraction` calculates the proportion of sunlit leaves in each vegetation layer. Function `light_cohortSunlitShadeAbsorbedRadiation` calculates the amount of radiation absorved by cohort and vegetation layers, while differentiating between sunlit and shade leaves.

## Usage

```
light_layerIrradianceFraction(LAIme, LAImd, LAImx, k, alpha,
                              trunkExtinctionFraction = 0.1)
light_layerIrradianceFractionBottomUp(LAIme, LAImd, LAImx, k, alpha,
                              trunkExtinctionFraction = 0.1)
light_layerSunlitFraction(LAIme, LAImd, kb)
light_cohortSunlitShadeAbsorbedRadiation(Ib0, Id0, Ibf, Idf, beta,
                                         LAIme, LAImd,
                                         kb, kd, alpha, gamma)
light_instantaneousLightExtinctionAbsortion(LAIme, LAImd, LAImx,
                                            kPAR, alphaSWR, gammaSWR,
                                            ddd, ntimesteps = 24,
                                            trunkExtinctionFraction = 0.1)
light_longwaveRadiationSHAW(LAIme, LAImd, LAImx,
                            LWRatm, Tsoil, Tair, trunkExtinctionFraction = 0.1)
light_cohortAbsorbedSWRFraction(z, x, SpParams, gdd = NA)
light_PARground(x, SpParams, gdd = NA, mode = "MED")
light_SWRground(x, SpParams, gdd = NA, mode = "MED")
light_PARcohort(x, SpParams, gdd = NA, mode = "MED")
```

## Arguments

| | |
|---|---|
| `LAIme` | A numeric matrix of live expanded LAI values per vegetation layer (row) and cohort (column). |
| `LAImd` | A numeric matrix of dead LAI values per vegetation layer (row) and cohort (column). |
| `LAImx` | A numeric matrix of maximum LAI values per vegetation layer (row) and cohort (column). |
| `k` | A vector of light extinction coefficients. |
| `kb` | A vector of direct light extinction coefficients. |
| `kd` | A vector of diffuse light extinction coefficients. |
| `Ib0` | Above-canopy direct incident radiation. |

| | |
|---|---|
| Id0 | Above-canopy diffuse incident radiation. |
| Ibf | Fraction of above-canopy direct radiation reaching each vegetation layer. |
| Idf | Fraction of above-canopy diffuse radiation reaching each vegetation layer. |
| alpha | A vecfor of leaf absorbance by species. |
| beta | Solar elevation (in radians). |
| gamma | Vector of canopy reflectance values. |
| kPAR | A vector of visible light extinction coefficients for each cohort. |
| alphaSWR | A vecfor of hort-wave absorbance coefficients for each cohort. |
| gammaSWR | A vector of short-wave reflectance coefficients (albedo) for each cohort. |
| ddd | A dataframe with direct and diffuse radiation for different subdaily time steps (see function radiation_directDiffuseDay in package meteoland). |
| ntimesteps | Number of subdaily time steps. |
| trunkExtinctionFraction | Fraction of extinction due to trunks (for winter deciduous forests). |
| LWRatm | Atmospheric downward long-wave radiation (W/m2). |
| Tsoil | Soil temperature (Celsius). |
| Tair | Canopy layer air temperature vector (Celsius). |
| x | An object of class forest |
| SpParams | A data frame with species parameters (see SpParamsMED). |
| z | A numeric vector with height values. |
| gdd | Growth degree days. |
| mode | Calculation mode, either "MED" or "US". |

## Details

Functions for short-wave radiation are adapted from Anten & Bastiaans (2016), whereas long-wave radiation balance follows Flerchinger et al. (2009). Vegetation layers are assumed to be ordered from bottom to top.

## Value

Functions light_layerIrradianceFraction, light_layerIrradianceFractionBottomUp and light_layerSunlitFraction return a numeric vector of length equal to the number of vegetation layers. Function light_cohortSunlitShadeAbsorbedRadiation returns a list with two elements (matrices): I_sunlit and I_shade.

`modelInput` *Input for simulation models*

---

## Description

Functions `forest2spwbInput` and `forest2growthInput` take an object of class `forest` and calculate input data for functions `spwb`, `pwb` and `growth`, respectively. Functions `spwbInput` and `growthInput` do the same but starting from different input data. Function `forest2aboveground` calculates aboveground variables that may be used in `spwbInput` and `growthInput` functions. Function `forest2belowground` calculates belowground fine root distribution.

## Usage

```
forest2aboveground(x, SpParams, gdd = NA, mode = "MED")
forest2belowground(x, soil)
forest2growthInput(x, soil, SpParams, control)
forest2spwbInput(x, soil, SpParams, control, mode = "MED")
growthInput(above,  Z50, Z95, soil, SpParams, control)
spwbInput(above,  Z50, Z95, soil, SpParams, control)
```

## Arguments

| | |
|---|---|
| `x` | An object of class `forest`. |
| `SpParams` | A data frame with species parameters (see `SpParamsDefinition` and `SpParamsMED`). |
| `gdd` | Growth degree days to account for leaf phenology effects (in Celsius). This should be left `NA` in most applications. |

| | |
|---|---|
| mode | Calculation mode, either "MED" or "US". |
| soil | An object of class soil. |
| control | A list with default control parameters (see defaultControl). |
| above | A data frame with aboveground plant information (see the return value of forest2aboveground below). In the case of spwbInput the variables should include SP, N, LAI_live, LAI_dead, H and CR. In the case of growthInput variables should include DBH and Cover. |
| Z50, Z95 | Numeric vectors with cohort depths (in mm) corresponding to 50% and 95% of fine roots. |

## Details

Functions forest2spwbInput and forest2aboveground extracts height and species identity from plant cohorts of x, and calculate leaf area index and crown ratio.forest2spwbInput also calculates the distribution of fine roots across soil. Both forest2spwbInput and spwbInput find parameter values for each plant cohort according to the parameters of its species as specified in SpParams. If control$transpirationMode = "Sperry" the functions also estimate the maximum conductance of rhizosphere, root xylem and stem xylem elements.

## Value

Function forest2aboveground() returns a data frame with the following columns (rows are identified as specified by function plant_ID):

- SP: Species identity (an integer) (first species is 0).
- N: Cohort density (ind/ha) (see function plant_density).
- DBH: Tree diameter at breast height (cm).
- H: Plant total height (cm).
- CR: Crown ratio (crown length to total height) (between 0 and 1).
- LAI_live: Live leaf area index (m2/m2) (one-side leaf area relative to plot area), includes leaves in winter dormant buds.
- LAI_expanded: Leaf area index of expanded leaves (m2/m2) (one-side leaf area relative to plot area).
- LAI_dead: Dead leaf area index (m2/m2) (one-side leaf area relative to plot area).

Functions forest2spwbInput() and spwbInput() return a list of class spwbInput with the following elements (rows of data frames are identified as specified by function plant_ID):

- control: List with control parameters (see defaultControl).
- canopy: A list of stand-level state variables.
- cohorts: A data frame with cohort information, with columns SP and Name.
- above: A data frame with columns H, CR and LAI (see function forest2aboveground).
- below: A data frame with columns Z50, Z95. If control$transpirationMode = "Sperry" additional columns are fineRootBiomass and coarseRootSoilVolume.
- belowLayers: A list. If control$transpirationMode = "Granier" it contains elements:

  - V: A matrix with the proportion of fine roots of each cohort (in rows) in each soil layer (in columns).
  - L: A matrix with the length of coarse roots of each cohort (in rows) in each soil layer (in columns).
  - Wpool: A matrix with the soil moisture relative to field capacity around the rhizosphere of each cohort (in rows) in each soil layer (in columns).

  If control$transpirationMode = "Sperry" there are the following additional elements:

  - VGrhizo_kmax: A matrix with maximum rhizosphere conductance values of each cohort (in rows) in each soil layer (in columns).
  - VGroot_kmax: A matrix with maximum root xylem conductance values of each cohort (in rows) in each soil layer (in columns).
  - RhizoPsi: A matrix with the water potential around the rhizosphere of each cohort (in rows) in each soil layer (in columns).

- paramsPhenology: A data frame with leaf phenology parameters:
  - PhenologyType: Leaf phenology type.
  - LeafDuration: Leaf duration (in years).
  - Sgdd: Degree days needed for leaf budburst (for winter decideous species).
  - Tbgdd: Base temperature for the calculation of degree days to leaf budburst.
  - Ssen: Degree days corresponding to leaf senescence.
  - Phsen: Photoperiod corresponding to start counting senescence degree-days.
  - Tbsen: Base temperature for the calculation of degree days to leaf senescence.
- paramsAnatomy: A data frame with plant anatomy parameters for each cohort:
  - Hmax: Maximum plant height (cm).
  - Hmed: Median plant height (cm).
  - Al2As: Leaf area to sapwood area ratio (in m2·m-2).
  - Ar2Al: Fine root area to leaf area ratio (in m2·m-2).
  - SLA: Specific leaf area (mm2/mg = m2/kg).
  - LeafWidth: Leaf width (in cm).
  - LeafDensity: Density of leaf tissue (dry weight over volume).
  - WoodDensity: Density of wood tissue (dry weight over volume).
  - FineRootDensity: Density of fine root tissue (dry weight over volume).
  - SRL: Specific Root length (cm·g-1).
  - RLD: Root length density (cm·cm-3).
  - r635: Ratio between the weight of leaves plus branches and the weight of leaves alone for branches of 6.35 mm.
- paramsInterception: A data frame with rain interception and light extinction parameters for each cohort:
  - kPAR: PAR extinction coefficient.
  - g: Canopy water retention capacity per LAI unit (mm/LAI).

  If control$transpirationMode = "Sperry" additional columns are:

  - gammaSWR: Reflectance (albedo) coefficient for SWR .
  - alphaSWR: Absorbance coefficient for SWR .

- paramsTranspiration: A data frame with parameters for transpiration and photosynthesis. If control$transpirationMode = "Granier", columns are:
  - Gswmin: Minimum stomatal conductance to water vapor (in mol H2O·m-2·s-1).
  - Tmax_LAI: Coefficient relating LAI with the ratio of maximum transpiration over potential evapotranspiration.
  - Tmax_LAIsq: Coefficient relating squared LAI with the ratio of maximum transpiration over potential evapotranspiration.
  - Psi_Extract: Water potential corresponding to 50% relative conductance (in MPa).
  - Psi_Critic: Water potential corresponding to 50% of stem cavitation (in MPa).
  - WUE: Daily water use efficiency (gross photosynthesis over transpiration) under no light, water or CO2 limitations and VPD = 1kPa (g C/mm water).
  - WUE_par: Coefficient regulating the influence of % PAR on gross photosynthesis.
  - WUE_par: Coefficient regulating the influence of atmospheric CO2 concentration on gross photosynthesis.
  - WUE_par: Coefficient regulating the influence of vapor pressure deficit (VPD) on gross photosynthesis.

  If control$transpirationMode = "Sperry" columns are:
  - Gswmin: Minimum stomatal conductance to water vapor (in mol H2O·m-2·s-1).
  - Gswmax: Maximum stomatal conductance to water vapor (in mol H2O·m-2·s-1).
  - Vmax298: Maximum Rubisco carboxilation rate at 25ºC (in micromol CO2·s-1·m-2).
  - Jmax298: Maximum rate of electron transport at 25ºC (in micromol photons·s-1·m-2).
  - Kmax_stemxylem: Sapwood-specific hydraulic conductivity of stem xylem (in kg H2O·s-1·m-2).
  - Kmax_rootxylem: Sapwood-specific hydraulic conductivity of root xylem (in kg H2O·s-1·m-2).
  - VCleaf_kmax: Maximum leaf hydraulic conductance.
  - VCleaf_c, VCleaf_d: Parameters of the leaf vulnerability curve.
  - VCstem_kmax: Maximum stem xylem conductance.
  - VCstem_c, VCstem_d: Parameters of the stem xylem vulnerability curve.
  - VCroot_c, VCroot_d: Parameters of the root xylem vulnerability curve.
  - Plant_kmax: Maximum whole-plant conductance.
- paramsWaterStorage: A data frame with plant water storage parameters for each cohort:
  - LeafPI0: Osmotic potential at full turgor of leaves (MPa).
  - LeafEPS: Modulus of elasticity (capacity of the cell wall to resist changes in volume in response to changes in turgor) of leaves (MPa).
  - LeafAF: Apoplastic fraction (proportion of water outside the living cells) in leaves.
  - Vleaf: Storage water capacity in leaves, per leaf area (L/m2).
  - StemPI0: Osmotic potential at full turgor of symplastic xylem tissue (MPa).
  - StemEPS: Modulus of elasticity (capacity of the cell wall to resist changes in volume in response to changes in turgor) of symplastic xylem tissue (Mpa).
  - StemAF: Apoplastic fraction (proportion of water outside the living cells) in stem xylem.
  - Vstem: Storage water capacity in sapwood, per leaf area (L/m2).
- internalPhenology and internalWater: data frames to store internal state variables.

Functions forest2growthInput and growthInput return a list of class growthInput with the same elements as spwbInput, but with additional information.

- Element above includes the following additional columns:
  - LA_live: Live leaf area per individual (m2/ind).
  - LA_dead: Dead leaf area per individual (m2/ind).
  - SA: Live sapwood area per individual (cm2/ind).
- paramsGrowth: A data frame with growth parameters for each cohort:
  - RERleaf: Maintenance respiration rates (at 20ºC) for leaves (in g gluc·g dry-1·day-1).
  - RERsapwood: Maintenance respiration rates (at 20ºC) for sapwood (in g gluc·g dry-1·day-1).
  - RERfineroot: Maintenance respiration rates (at 20ºC) for fine roots (in g gluc·g dry-1·day-1).
  - CCleaf: Leaf construction costs (in g gluc·g dry-1).
  - CCsapwood: Sapwood construction costs (in g gluc·g dry-1).
  - CCfineroot: Fine root construction costs (in g gluc·g dry-1).
  - RGRleafmax: Maximum leaf relative growth rate (in m2·cm-2·day-1).
  - RGRsapwoodmax: Maximum sapwood relative growth rate (in cm2·cm-2·day-1).
  - RGRfinerootmax: Maximum fine root relative growth rate (in g dry·g dry-1·day-1).
  - SRsapwood: Sapwood daily senescence rate (in day-1).
  - SRfineroot: Fine root daily senescence rate (in day-1).
  - RSSG: Minimum relative starch for sapwood growth (proportion).
  - fHDmin: Minimum value of the height-to-diameter ratio (dimensionless).
  - fHDmax: Maximum value of the height-to-diameter ratio (dimensionless).
  - WoodC: Wood carbon content per dry weight (g C /g dry).
  - MortalityBaselineRate: Deterministic proportion or probability specifying the baseline reduction of cohort's density occurring in a year.
- paramsAllometry: A data frame with allometric parameters for each cohort:
  - Aash: Regression coefficient relating the square of shrub height with shrub area.
  - Absh, Bbsh: Allometric coefficients relating phytovolume with dry weight of shrub individuals.
  - Acr, B1cr, B2cr, B3cr, C1cr, C2cr: Regression coefficients used to calculate crown ratio of trees.
  - Acw, Bcw: Regression coefficients used to calculated crown width of trees.
- internalAllocation: A data frame with internal allocation variables for each cohort:
  - allocationTarget: Value of the allocation target variable.
  - leafAreaTarget: Target leaf area (m2) per individual.
  - fineRootBiomassTarget: Target fine root biomass (g dry) per individual (only if transpirationMode = "Sperry").
- internalCarbon and internalRings: data structures to store other internal state variables.

---

# modifyParams *Modify parameters*

---

## Description

Routines to modify species parameter table or model input objects

## Usage

```
modifySpParams(SpParams, customParams, subsetSpecies = TRUE)
modifyCohortParams(x, customParams, verbose = TRUE)
modifyInputParams(x, customParams, verbose = TRUE)
```

## Arguments

| | |
|---|---|
| x | A model input object of class spwbInput or growthInput. |
| SpParams | A species parameter data frame, typically SpParamsMED. |
| customParams | A data frame or a named vector with new parameter values (see details). |
| subsetSpecies | A flag to indicate that the output data frame should include only those species mentioned in customParams. |
| verbose | A flag to indicate that messages should be printed on the console. |

## Details

When calling function modifySpParams, customParams should be a data frame with as many rows as species and as many columns as parameters to modify, plus a column called 'SpIndex' to match species between the two tables.

When calling modifyCohortParams, customParams can be a data frame with as many rows as cohorts and as many columns as parameters to modify, plus a column called 'Cohort' which will be matched with the cohort names given by spwbInput or growthInput. Alternatively, customParams can be a named list or named numeric vector as for modifyInputParams.

When calling modifyInputParams, customParams must be either a named list or a named numeric vector. Cohort parameters are specified using the syntax "<cohortName>/<paramName>" for names (e.g. "T2_176/Z50" to modify parameter 'Z50' of cohort 'T2_176'). Soil layer parameters are specified using the syntax "<paramName>@#layer" for names, where #layer is the layer index (e.g. "rfc@1" will modify the rock fragment content of soil layer 1). Control parameters are specified using either "<paramName>" (e.g "phloemConductanceFactor") or "<paramName>$<subParamName>" (e.g "maximumRelativeGrowthRates$leaf"). It may seem unnecessary to modify soil or control parameters via a function, but modifyInputParams is called from optimization functions (see optimization).

## Value

Function modifySpParams returns a modified species parameter data frame.

Functions modifyCohortParams and modifyInputParams return a modified spwbInput or growthInput object. Note that modifications may affect other parameters beyond those indicated in customParams, as a result of parameter dependencies (see examples).

Mortality *Mortality*

---

## Description

A simple function to determine a daily mortality likelihood according to the value of a stress variable.

## Usage

```
mortality_dailyProbability(basalMortalityRate, stressValue,
                           stressThreshold, minValue = 0.0,
                           exponent = 10.0)
```

## Arguments

| | |
|---|---|
| basalMortalityRate | Basal daily mortality rate per individual. |
| stressValue | Current value of the stress variable (lower values indicate stronger stress). |
| stressThreshold | Threshold to indicate that lower values increase mortality likelihood. |
| minValue | Minimum value of the stress variable (i.e. maximum stress), corresponding to probability of mortality equal to 1. |
| exponent | Coefficient modulating the steepness of the relationship. |

## Value

Returns a probability (between 0 and 1).

# optimization *Multiple model runs and function factories for optimization routines*

---

## Description

Function factories to generate functions to be used in model calibration, uncertainty or sensitivity analysis.

## Usage

```
multiple_runs(parMatrix, x,
              meteo, latitude,
              elevation = NA, slope = NA, aspect = NA,
              summary_function = NULL, args = NULL,
              verbose = TRUE)
optimization_function(parNames, x,
                      meteo, latitude,
                      elevation = NA, slope = NA, aspect = NA,
                      summary_function, args= NULL)
optimization_evaluation_function(parNames, x,
                      meteo, latitude,
                      elevation = NA, slope = NA, aspect = NA,
                      measuredData, type = "SWC", cohorts = NULL,
                      temporalResolution = "day",
                      metric = "loglikelihood")
optimization_multicohort_function(cohortParNames, cohortNames, x,
                      meteo, latitude,
                      otherParNames = NULL,
                      elevation = NA, slope = NA, aspect = NA,
                      summary_function, args= NULL)
optimization_evaluation_multicohort_function(cohortParNames, cohortNames, x,
                      meteo, latitude,
                      otherParNames = NULL,
                      elevation = NA, slope = NA, aspect = NA,
                      measuredData, type = "SWC", cohorts = cohortNames,
                      temporalResolution = "day",
                      metric = "loglikelihood")
```

## Arguments

| | |
|---|---|
| parMatrix | A matrix of parameter values with runs in rows and parameters in columns. Column names should follow parameter modification naming rules (see examples and naming rules in modifyInputParams). |
| parNames | A string vector of parameter names (see examples and naming rules in modifyInputParams). |
| x | An object of class spwbInput or growthInput. |
| meteo, latitude, elevation, slope, aspect | Additional parameters to simulation functions spwb or growth. |
| verbose | A flag to indicate extra console output. |
| measuredData | A data frame with observed/measured values. Dates should be in row names, whereas columns should be named according to the type of output to be evaluated (see details). |
| type | A string with the kind of model output to be evaluated. Accepted values are "SWC" (soil moisture content), "REW" relative extractable water, "ETR" (total evapotranspiration), "E" (transpiration per leaf area), "LFMC" (live fuel moisture content) and "WP" (plant water potentials). |

`cohorts` A string or a vector of strings with the cohorts to be compared (e.g. "T1_68"). If several cohort names are provided, the function `optimization_cohorts_function` evaluates the performance for each one and provides the mean value. If `NULL` results for the first cohort will be evaluated.

`temporalResolution` A string to indicate the temporal resolution of the model evaluation, which can be "day", "week", "month" or "year". Observed and modelled values are aggregated temporally (using either means or sums) before comparison.

`metric` An evaluation metric (see `evaluation_metric`).

`summary_function` A function whose input is the result of `spwb` or `growth`. The function must return a numeric scalar in the case of `optimization_function`, but is not restricted in the case of `multiple_runs`.

`args` A list of additional arguments of `optimization_function`.

`cohortParNames` A string vector of vegetation parameter names for cohorts (e.g. 'Z95' or 'psiExtract').

`cohortNames` A string vector of cohort names. All cohorts will be given the same parameter values for each parameter in 'cohortParNames'.

`otherParNames` A string vector of parameter names (see examples and naming rules in `modifyInputParams`) for non-vegetation parameters (i.e. control parameters and soil parameters).

## Details

See `evaluation` for details regarding how to specify measured data.

Functions produced by these function factories should be useful for sensitivity analyses using package 'sensitivity'.

Parameter naming (i.e. `parNames`) should follow the rules specified in section details of `modifyInputParams`. The exception to the naming rules applies when multiple cohorts are to be modified to the same values with functions `optimization_multicohort_function` and `optimization_evaluation_multicohort_function`. Then, only a vector of parameter names is supplied for `cohortParNames`.

## Value

Function `multiple_runs` returns a list, whose elements are either the result of calling simulation models or the result of calling `summary_function` afterwards.

Function `optimization_function` returns a function whose parameters are parameter values and whose return is a prediction scalar (e.g. total transpiration).

Function `optimization_evaluation_function` returns a function whose parameters are parameter values and whose return is an evaluation metric (e.g. loglikelihood of the data observations given model predictions). If evaluation data contains information for different cohorts (e.g. plant water potentials or transpiration rates) then the evaluation is performed for each cohort and the metrics are averaged.

Function `optimization_multicohorts_function` returns a function whose parameters are parameter values and whose return is a prediction scalar (e.g. total transpiration). The difference with `optimization_function` is that multiple cohorts are set to the same parameter values.

Function optimization_evaluation_multicohort_function returns a function whose parameters are parameter values and whose return is an evaluation metric (e.g. loglikelihood of the data observations given model predictions). If evaluation data contains information for different cohorts (e.g. plant water potentials or transpiration rates) then the evaluation is performed for each cohort and the metrics are averaged. The difference with optimization_evaluation_function is that multiple cohorts are set to the same parameter values.

oef(parMatrix)

## End(Not run)
```

---

`Parameter means` *Parameter average values*

---

## Description

Internal data set with parameter averages for taxonomic families. This is used by input initialization functions to provide suitable parameter values when missing from species parameter tables.

## Format

Data frame `trait_family_means` has taxonomic families in rows and parameter names as columns.

## Source

Same sources as SpParamsMED

## See Also

SpParamsMED, spwbInput

## Examples

```
medfate:::trait_family_means
```

---

pheno_updateLeaves *Leaf phenology*

---

## Description

Function pheno_leafDevelopmentStatus returns the expanded status (0 to 1) of leaves according to the growth degree days required to start bud burst and leaf unfolding, as dictated by a simple ecodormancy (one-phase) model (Chuine et al. 2013). Function pheno_leafSenescenceStatus returns the 0/1 senescence status of leaves according to the one-phase senescence model of Delpierre et al. (2009) on the basis of photoperiod and temperature. Function pheno_updateLeaves updates the status of expanded leaves and dead leaves of object x given the photoperiod, temperature and wind of a given day. It applies the development model for 1 < doy < 180 and the senescence model for 181 > doy > 365.

## Usage

```
pheno_leafDevelopmentStatus(Sgdd, gdd, unfoldingDD = 300)
pheno_leafSenescenceStatus(Ssen, sen)
pheno_updatePhenology(x, doy, photoperiod, tmean)
pheno_updateLeaves(x, wind, fromGrowthModel)
```

## Arguments

| | |
|---|---|
| Sgdd | Degree days required for leaf budburst (in Celsius). |
| gdd | Cumulative degree days (in Celsius) |
| unfoldingDD | Degree-days for complete leaf unfolding after budburst has occurred. |
| Ssen | Threshold to start leaf senescence. |
| sen | Cumulative senescence variable. |
| x | An object of class spwbInput. |
| doy | Day of the year. |
| photoperiod | Day length (in hours). |
| tmean | Average day temperature (in Celsius). |
| wind | Average day wind speed (in m/s). |
| fromGrowthModel | Boolean flag to indicate that routine is called from growth simulation function. |

## Value

Function pheno_leafDevelopmentStatus returns a vector of values between 0 and 1, whereas function pheno_leafSenescenceStatus returns a vector of 0 (senescent) and 1 (expanded) values. The other two functions do not return any value (see details).

## Note

Functions `pheno_updatePhenology` and `pheno_updateLeaves` modify the input object `x`. The first modifies phenological state and the second modifies the leaf area accordingly.

```

```
photo_multilayerPhotosynthesisFunction(E, psiLeaf, Catm, Patm, Tair, vpa,
                                       SLarea, SHarea, u,
                                       absRadSL, absRadSH, QSL, QSH,
                                       Vmax298, Jmax298, leafWidth = 1.0,
                                       verbose = FALSE)
```

## Arguments

| | |
|---|---|
| Tleaf | Leaf temperature (in ºC). |
| Oi | Oxigen concentration (mmol*mol-1). |
| Vmax298, Vmax298SL, Vmax298SH | Maximum Rubisco carboxylation rate per leaf area at 298ºK (i.e. 25 ºC) (micromol*s-1*m-2) (for each canopy layer in the case of photo_multilayerPhotosynthesisFunction). 'SH' stands for shade leaves, whereas 'SL' stands for sunlit leaves. |
| Jmax298, Jmax298SL, Jmax298SH | Maximum electron transport rate per leaf area at 298ºK (i.e. 25 ºC) (micromol*s-1*m-2) (for each canopy layer in the case of photo_multilayerPhotosynthesisFunction). 'SH' stands for shade leaves, whereas 'SL' stands for sunlit leaves. |
| Q | Active photon flux density (micromol * s-1 * m-2). |
| Ci | CO2 internal concentration (micromol * mol-1). |
| GT | CO2 saturation point corrected by temperature (micromol * mol-1). |
| Jmax | Maximum electron transport rate per leaf area (micromol*s-1*m-2). |
| Km | Km = Kc*(1.0+(Oi/Ko)) - Michaelis-Menten term corrected by temperature (in micromol * mol-1). |
| Vmax | Maximum Rubisco carboxylation rate per leaf area (micromol*s-1*m-2). |
| Catm | CO2 air concentration (micromol * mol-1). |
| Gc | CO2 leaf (stomatal) conductance (mol * s-1 * m-2). |
| E | Transpiration flow rate per leaf area (mmol*s-1*m-2). |
| psiLeaf | Leaf water potential (MPa). |
| Patm | Atmospheric air pressure (in kPa). |
| Tair | Air temperature (in ºC). |
| vpa | Vapour pressure deficit (in kPa). |
| u | Wind speed above the leaf boundary (in m/s) (for each canopy layer in the case of photo_multilayerPhotosynthesisFunction). |
| absRad | Absorbed long- and short-wave radiation (in W*m^-2). |
| SWRabs | Absorbed short-wave radiation (in W·m-2). |
| LWRnet | Net long-wave radiation balance (in W·m-2). |
| leafWidth | Leaf width (in cm). |
| refLeafArea | Leaf reference area. |
| verbose | Boolean flag to indicate console output. |
| SLarea, SHarea | Leaf area index of sunlit/shade leaves (for each canopy layer in the case of photo_multilayerPhotosynthesisFunction). |

absRadSL, absRadSH
: Instantaneous absorbed radiation (W·m-2) per unit of sunlit/shade leaf area (for each canopy layer in the case of photo_multilayerPhotosynthesisFunction).

QSL, QSH
: Active photon flux density (micromol * s-1 * m-2) per unit of sunlit/shade leaf area (for each canopy layer in the case of photo_multilayerPhotosynthesisFunction).

## Details

Details of the photosynthesis submodel are given in a vignette.

## Value

Values returned for each function are:

- photo_GammaTemp: CO2 compensation concentration (micromol * mol-1).
- photo_KmTemp: Michaelis-Menten coefficients of Rubisco for Carbon (micromol * mol-1) and Oxigen (mmol * mol-1).
- photo_VmaxTemp: Temperature correction of Vmax298.
- photo_JmaxTemp: Temperature correction of Jmax298.
- photo_electronLimitedPhotosynthesis: Electron-limited photosynthesis (micromol*s-1*m-2) following Farquhar et al. (1980).
- photo_rubiscoLimitedPhotosynthesis: Rubisco-limited photosynthesis (micromol*s-1*m-2) following Farquhar et al. (1980).
- photo_photosynthesis: Calculates gross photosynthesis (micromol*s-1*m-2) following (Farquhar et al. (1980) and Collatz et al (1991).
- photo_leafPhotosynthesisFunction: Returns a data frame with the following columns:
  - LeafTemperature: Leaf temperature (ºC).
  - LeafVPD: Leaf vapor pressure deficit (kPa).
  - LeafCi: Internal CO2 concentration (micromol * mol-1).
  - Gsw: Leaf stomatal conductance to water vapor (mol * s-1 * m-2).
  - GrossPhotosynthesis: Gross photosynthesis (micromol*s-1*m-2).
  - NetPhotosynthesis: Net photosynthesis, after discounting autotrophic respiration (micromol*s-1*m-2).
- photo_sunshadePhotosynthesisFunction: Returns a data frame with the following columns:
  - GrossPhotosynthesis: Gross photosynthesis (micromol*s-1*m-2).
  - NetPhotosynthesis: Net photosynthesis, after discounting autotrophic respiration (micromol*s-1*m-2).
  - LeafCiSL: Sunlit leaf internal CO2 concentration (micromol * mol-1).
  - LeafCiSH: Shade leaf internal CO2 concentration (micromol * mol-1).
  - LeafTempSL: Sunlit leaf temperature (ºC).
  - LeafTempSH: Shade leaf temperature (ºC).
  - LeafVPDSL: Sunlit leaf vapor pressure deficit (kPa).
  - LeafVPDSH: Shade leaf vapor pressure deficit (kPa).
- photo_multilayerPhotosynthesisFunction: Return a data frame with the following columns:

- `GrossPhotosynthesis`: Gross photosynthesis (micromol*s-1*m-2).
- `NetPhotosynthesis`: Net photosynthesis, after discounting autotrophic respiration (micromol*s-1*m-2).

## Description

Functions to calculate attributes of plants in a `forest` object.

## Usage

```
plant_basalArea(x)
plant_largerTreeBasalArea(x)
plant_characterParameter(x, SpParams, parName)
plant_cover(x, SpParams, mode = "MED")
plant_crownBaseHeight(x, SpParams, mode = "MED")
plant_crownLength(x, SpParams, mode = "MED")
plant_crownRatio(x, SpParams, mode = "MED")
plant_density(x, SpParams, mode = "MED")
plant_equilibriumLeafLitter(x, SpParams, AET = 800, mode = "MED")
```

```
plant_equilibriumSmallBranchLitter(x, SpParams,
                                   smallBranchDecompositionRate = 0.81, mode = "MED")
plant_foliarBiomass(x, SpParams, gdd = NA, mode = "MED")
plant_fuel(x, SpParams, gdd = NA, includeDead = TRUE, mode = "MED")
plant_height(x)
plant_ID(x, treeOffset = 0, shrubOffset = 0)
plant_LAI(x, SpParams, gdd = NA, mode = "MED")
plant_individualArea(x, SpParams, mode = "MED")
plant_parameter(x, SpParams, parName, fillMissing = TRUE)
plant_phytovolume(x, SpParams)
plant_species(x)
plant_speciesName(x, SpParams)
```

## Arguments

| | |
|---|---|
| x | An object of class forest. |
| SpParams | A data frame with species parameters (see SpParamsMED). |
| parName | A string with a parameter name. |
| mode | Calculation mode, either "MED" or "US". |
| gdd | Growth degree days (to account for leaf phenology effects). |
| AET | Actual annual evapotranspiration (in mm). |
| smallBranchDecompositionRate | Decomposition rate of small branches. |
| includeDead | A flag to indicate that standing dead fuels (dead branches) are included. |
| treeOffset, shrubOffset | Integers to offset cohort IDs. |
| fillMissing | A boolean flag to try imputation on missing values. |

## Value

A vector with values for each plant of the input forest object:

- plant_basalArea: Tree basal area (m2/ha).
- plant_largerTreeBasalArea: Basal area (m2/ha) of trees larger (in diameter) than the tree. Half of the trees of the same record are included.
- plant_characterParameter: The parameter values of each plant, as strings.
- plant_cover: Shrub cover (in percent).
- plant_crownBaseHeight: The height corresponding to the start of the crown (in cm).
- plant_crownLength: The difference between crown base height and total height (in cm).
- plant_crownRatio: The ratio between crown length and total height (between 0 and 1).
- plant_density: Plant density (ind/ha). Tree density is directly taken from the forest object, while the shrub density is estimated from cover and height by calculating the area of a single individual.
- plant_equilibriumLeafLitter: Litter biomass of leaves at equilibrium (in kg/m2).

- `plant_equilibriumSmallBranchLitter`: Litter biomass of small branches (< 6.35 mm diameter) at equilibrium (in kg/m2).
- `plant_foliarBiomass`: Standing biomass of leaves (in kg/m2).
- `plant_fuel`: Fine fuel load (in kg/m2).
- `plant_height`: Total height (in cm).
- `plant_ID`: Cohort coding for simulation functions (concatenation of 'T' (Trees) or 'S' (Shrub), cohort index and species index).
- `plant_LAI`: Leaf area index (m2/m2).
- `plant_individualArea`: Area (m2) occupied by a shrub individual.
- `plant_parameter`: The parameter values of each plant, as numeric.
- `plant_phytovolume`: Shrub phytovolume (m3/m2).
- `plant_species`: Species identity integer (indices start with 0).
- `plant_speciesName`: String with species taxonomic name (or a functional group).

plot.forest *Plot forest attributes*

## Description

Convenient wrappers for vertical forest profiles (see vprofile_leafAreaDensity).

## Usage

```
## S3 method for class 'forest'
plot(x, SpParams, type = "LeafAreaDensity",
                      byCohorts = FALSE, bySpecies = FALSE, ...)
## S3 method for class 'forest'
shinyplot(x, SpParams, ...)
```

## Arguments

| | |
|---|---|
| x | An object of class forest. |
| SpParams | A data frame with species parameters (see SpParamsMED). |
| type | A string of the plot type: "LeafAreaDensity", "RootDistribution", "FuelBulkDensity", "PARExtinction", "SWRExtinction" or "WindExtinction". |
| byCohorts | Flag to separate profiles for each cohort. |
| bySpecies | Flag to aggregate results by species. |
| ... | Additional parameters to vertical profiles |

## Value

A ggplot or a shiny application, depending on the function.

## Author(s)

Miquel De Cáceres Ainsa, CREAF

```

## Arguments

| | |
|---|---|
| x | An object of class spwb, pwb, growth or fordyn. |
| type | The information to be plotted (see details) |
| cohorts | An integer, boolean or character vector to select the plant cohorts to be plotted. If cohorts = "T" (resp. cohorts = "S") then all tree (resp. shrub) cohorts will be displayed. |
| bySpecies | Allows aggregating output by species, before drawing plots (only has an effect with some values of type). Aggregation can involve a sum (as for plant lai or transpiration) or a LAI-weighted mean (as for plant stress or plant water potential), where LAI values are those of LAIlive. |

| | |
|---|---|
| dates | A Date vector with a subset of dates to be plotted. |
| subdaily | Whether subdaily results should be shown, only for simulations using transpirationMode = "Sperry" and having set subdailyResults = TRUE in the simulation control object. If subdaily = TRUE, then the valid strings for type are listed in plot.spwb_day. |
| xlim | Range of values for x. |
| ylim | Range of values for y. |
| xlab | x-axis label. |
| ylab | y-axis label. |
| summary.freq | Frequency of summary statistics (see cut.Date). |
| ... | Additional parameters for function plot (not used). |

## Details

The following plots are currently available for spwb (most of them also for pwb):

- "PET_Precipitation": Potential evapotranspiration and Precipitation.
- "PET_NetRain": Potential evapotranspiration and Net rainfall.
- "Snow": Snow precipitation and snowpack dynamics.
- "Export": Water exported through deep drainage and surface runoff.
- "Evapotranspiration": Plant transpiration and soil evaporation.
- "SoilPsi": Soil water potential.
- "SoilRWC": Soil relative water content (in percent of field capacity).
- "SoilTheta": Soil moisture water content (in percent volume).
- "SoilVol": Soil water volumetric content (in mm).
- "PlantExtraction": Water extracted by plants from each soil layer.
- "HydraulicRedistribution": Water added to each soil layer coming from other soil layers, transported through the plant hydraulic network.
- "WTD": Water table depth.
- "LAI": Expanded and dead leaf area index of the whole stand.
- "PlantLAI": Plant cohort leaf area index (expanded leaves).
- "PlantLAIlive": Plant cohort leaf area index ("live" leaves).
- "PlantStress": Plant cohort average daily drought stress.
- "PlantTranspiration": Plant cohort transpiration.
- "TranspirationPerLeaf": Plant cohort transpiration per leaf area.
- "PlantGrossPhotosynthesis": Plant cohort photosynthesis.
- "GrossPhotosynthesisPerLeaf": Plant cohort photosynthesis per leaf area.
- "StemRWC": Average daily stem relative water content.
- "LeafRWC": Average daily leaf relative water content.
- "LFMC": Live fuel moisture content.

The following plots are available for spwb and pwb *only if* `transpirationMode = "Granier"`:

- `"PlantPsi"`: Plant cohort water potential.
- `"FPAR"`: Fraction of PAR at the canopy level of each plant cohort.
- `"AbsorbedSWRFraction"`: Fraction of SWR absorbed by each plant cohort.

The following plots are available for spwb and pwb *only if* `transpirationMode = "Sperry"`:

- `"SoilPlantConductance"`: Average instantaneous overall soil plant conductance (calculated as the derivative of the supply function).
- `"LeafPsiMin"`: Midday leaf water potential.
- `"LeafPsiMax"`: Pre-dawn leaf water potential.
- `"LeafPsiRange"`: Range of leaf water potential.
- `"LeafPsiMin_SL"`: Minimum water potential of sunlit leaves.
- `"LeafPsiMax_SL"`: Maximum water potential of sunlit leaves.
- `"LeafPsiMin_SH"`: Minimum water potential of shade leaves.
- `"LeafPsiMax_SH"`: Maximum water potential of shade leaves.
- `"TempMin_SL"`: Minimum temperature of sunlit leaves.
- `"TempMax_SL"`: Maximum temperature of sunlit leaves.
- `"TempMin_SH"`: Minimum temperature of shade leaves.
- `"TempMax_SH"`: Maximum temperature of shade leaves.
- `"GSWMin_SL"`: Minimum stomatal conductance of sunlit leaves.
- `"GSWMax_SL"`: Maximum stomatal conductance of sunlit leaves.
- `"GSWMin_SH"`: Minimum stomatal conductance of shade leaves.
- `"GSWMax_SH"`: Maximum stomatal conductance of shade leaves.
- `"StemPsi"`: Midday (upper) stem water potential.
- `"RootPsi"`: Midday root crown water potential.
- `"PlantNetPhotosynthesis"`: Plant cohort net photosynthesis.
- `"NetPhotosynthesisPerLeaf"`: Plant cohort net photosynthesis per leaf area.
- `"PlantWUE"`: Plant cohort daily water use efficiency.
- `"PlantAbsorbedSWR"`: Plant cohort absorbed short wave radiation.
- `"AbsorbedSWRPerLeaf"`: Plant cohort absorbed short wave radiation per leaf area.
- `"PlantNetLWR"`: Plant cohort net long wave radiation.
- `"NetLWRPerLeaf"`: Plant cohort net long wave radiation per leaf area.
- `"AirTemperature"`: Minimum/maximum/mean daily temperatures above canopy.
- `"CanopyTemperature"`: Minimum/maximum/mean daily temperatures inside canopy.
- `"SoilTemperature"`: Minimum/maximum/mean daily temperatures inside the first soil layer.
- `"CanopyEnergyBalance"`: Canopy energy balance components.
- `"SoilEnergyBalance"`: Soil energy balance components.

In addition to the former, the following plots are available for objects `growth` or `fordyn`:

- `"CarbonBalance"`: Stand-level carbon balance components.
- `"BiomassBalance"`: Stand-level biomass balance components.
- `"GrossPhotosynthesis"`: Gross photosynthesis rate per dry weight.
- `"MaintenanceRespiration"`: Maintenance respiration cost per dry weight.
- `"PhotosynthesisMaintenanceRatio"`: The ratio of gross photosynthesis over maintenance respiration.
- `"RootExudation"`: Root exudation rate per dry weight.
- `"LabileCarbonBalance"`: Labile carbon balance per dry weight.
- `"SugarLeaf"`: Sugar concentration in leaves.
- `"StarchLeaf"`: Starch concentration in leaves.
- `"SugarSapwood"`: Sugar concentration in sapwood.
- `"StarchSapwood"`: Starch concentration in sapwood.
- `"SugarTransport"`: Phloem sugar transport rate.
- `"StructuralBiomassBalance"`: Daily structural biomass balance (g dry · ind-2).
- `"LabileBiomassBalance"`: Daily labile biomass balance (g dry · ind-2).
- `"PlantBiomassBalance"`: Daily plant biomass balance, i.e. labile change + structural change (g dry · ind-2).
- `"MortalityBiomassLoss"`: Biomass loss due to mortality (g dry · m-2).
- `"PlantBiomassBalance"`: Daily cohort biomass balance (including mortality) (g dry · m-2).
- `"LeafBiomass"`: Leaf structural dry biomass per individual.
- `"SapwoodBiomass"`: Sapwood dry biomass per individual.
- `"FineRootBiomass"`: Fine root dry biomass per individual.
- `"SapwoodArea"`: Sapwood area per individual.
- `"LeafArea"`: Leaf area per individual.
- `"FineRootArea"`: Fine root area per individual (only for `transpirationMode = "Sperry"`).
- `"DBH"`: Diameter at breast height (in cm) for an average individual of each plant cohort.
- `"Height"`: Height (in cm) for an average individual of each plant cohort.
- `"SAgrowth"`: Sapwood area growth rate.
- `"LAgrowth"`: Leaf area growth rate.
- `"FRAgrowth"`: Fine root area growth rate (only for `transpirationMode = "Sperry"`).
- `"HuberValue"`: Ratio of leaf area to sapwood area.
- `"RootAreaLeafArea"`: Ratio of fine root area to leaf area (only for `transpirationMode = "Sperry"`).

Finally, the following plots are only available for `fordyn` simulation results:

- `"StandBasalArea"`: Stand basal area of living trees.
- `"StandDensity"`: Stand density of living trees.
- `"SpeciesBasalArea"`: Basal area of living trees by species.
- `"SpeciesDensity"`: Density of living trees by species.
- `"CohortBasalArea"`: Basal area of living trees by plant cohort.
- `"CohortDensity"`: Density of living trees by plant cohort.

---

## plot.spwb_day *Plots simulation results for one day*

---

### Description

Functions to plot the subdaily simulation results of spwb_day, growth_day or the transpiration calculations of transp_transpirationSperry.

### Usage

```
## S3 method for class 'growth_day'
plot(x, type="PlantTranspiration", bySpecies = FALSE,
                          xlim = NULL, ylim=NULL, xlab = NULL, ylab = NULL, ...)
## S3 method for class 'spwb_day'
plot(x, type="PlantTranspiration", bySpecies = FALSE,
```

```
                          xlim = NULL, ylim=NULL, xlab = NULL, ylab = NULL, ...)
## S3 method for class 'pwb_day'
plot(x, type="PlantTranspiration", bySpecies = FALSE,
                        xlim = NULL, ylim=NULL, xlab = NULL, ylab = NULL, ...)
```

## Arguments

| | |
|---|---|
| x | An object of class spwb_day, growth_day or pwb_day. |
| type | The information to be plotted (see details). |
| bySpecies | Allows aggregating output by species, before drawing plots. Aggregation can involve a sum (as for plant lai or transpiration) or a LAI-weighted mean (as for plant stress or plant water potential). |
| xlim | Range of values for x. |
| ylim | Range of values for y. |
| xlab | x-axis label. |
| ylab | y-axis label. |
| ... | Additional parameters for function plot. |

## Details

The following plots are available for spwb_day and pwb_day:

- "LeafPsi":Leaf water potential (for shade and sunlit leaves).
- "LeafPsiAverage":Average leaf water potential.
- "RootPsi":Root crown water potential.
- "StemPsi":(Upper) stem water potential.
- "StemPLC":(Average) percentage of loss conductance in the stem conduits.
- "StemRWC":(Average) relative water content in the stem.
- "LeafRWC":Relative water content in the leaf.
- "StemSympRWC":(Average) relative water content in the stem symplasm.
- "LeafSympRWC":Relative water content in the leaf symplasm.
- "SoilPlantConductance":Overall soil plant conductance (calculated as the derivative of the supply function).
- "PlantExtraction": Water extracted from each soil layer.
- "PlantTranspiration": Plant cohort transpiration per ground area.
- "TranspirationPerLeaf": Plant cohort transpiration per leaf area.
- "PlantGrossPhotosynthesis": Plant cohort gross photosynthesis per ground area.
- "GrossPhotosynthesisPerLeaf": Plant cohort gross photosynthesis per leaf area.
- "PlantNetPhotosynthesis": Plant cohort net photosynthesis per ground area.
- "NetPhotosynthesisPerLeaf": Plant cohort net photosynthesis per leaf area.
- "LeafTranspiration": Instantaneous transpiration per leaf area (differentiates sunlit and shade leaves).

- "LeafGrossPhotosynthesis": Instantaneous gross photosynthesis per leaf area (differentiates sunlit and shade leaves).
- "LeafNetPhotosynthesis": Instantaneous net photosynthesis per leaf area (differentiates sunlit and shade leaves).
- "LeafAbsorbedSWR": Absorbed short wave radiation per leaf area (differentiates sunlit and shade leaves).
- "LeafNetLWR": Net long wave radiation per leaf area (differentiates sunlit and shade leaves).
- "LeafCi": Leaf intercellular CO2 concentration (differentiates sunlit and shade leaves).
- "LeafIntrinsicWUE": Leaf intrinsic water use efficiency, i.e. the ratio between instantaneous photosynthesis and stomatal conductance (differentiates sunlit and shade leaves).
- "LeafVPD": Leaf vapour pressure deficit (differentiates sunlit and shade leaves).
- "LeafStomatalConductance": Leaf stomatal conductance to water vapour (differentiates sunlit and shade leaves).
- "LeafTemperature": Leaf temperature (differentiates sunlit and shade leaves).
- "Temperature": Above-canopy, inside-canopy and soil temperature.
- "CanopyEnergyBalance": Canopy energy balance components.
- "SoilEnergyBalance": Soil energy balance components.
- "PlantWaterBalance": Difference between water extraction from the soil and transpired water per ground area.
- "WaterBalancePerLeaf": Difference between water extraction from the soil and transpired water per leaf area.

And the following plots are additionally available for `growth_day`:

- "GrossPhotosynthesis": Gross photosynthesis rate per dry weight.
- "MaintenanceRespiration": Maintenance respiration cost per dry weight.
- "RootExudation": Root exudation rate per dry weight.
- "LabileCarbonBalance": Labile carbon balance per dry weight.
- "SugarLeaf": Sugar concentration in leaves.
- "StarchLeaf": Starch concentration in leaves.
- "SugarSapwood": Sugar concentration in sapwood.
- "StarchSapwood": Starch concentration in sapwood.
- "SugarTransport": Phloem sugar transport rate.

## Note

Only for soil plant water balance simulations using `transpirationMode = "Sperry"`. This function can be used to display subdaily dynamics of corresponding to single days on `spwb` runs, if control option `subdailyResults` is set to `TRUE`. See also option `subdaily` in `plot.spwb`.

## Author(s)

#Default species parameterization
data(SpParamsMED)

#Initialize control parameters
control = defaultControl("Granier")
control$ndailysteps = 24

#Initialize soil with default soil params (2 layers)
examplesoil = soil(defaultSoilParams(2), W=c(0.5,0.5))

#Switch to 'Sperry' transpiration mode
control = defaultControl("Sperry")

#Simulate one day only
x2 = forest2spwbInput(exampleforestMED,examplesoil, SpParamsMED, control)
d = 100
sd2<-spwb_day(x2, rownames(examplemeteo)[d],
              examplemeteo$MinTemperature[d], examplemeteo$MaxTemperature[d],
              examplemeteo$MinRelativeHumidity[d], examplemeteo$MaxRelativeHumidity[d],
              examplemeteo$Radiation[d], examplemeteo$WindSpeed[d],
              latitude = 41.82592, elevation = 100,
              slope= 0, aspect = 0, prec = examplemeteo$Precipitation[d])

#Display transpiration for subdaily steps
plot(sd2, "PlantTranspiration")
```

---

# recruitment *Plant recruitment*

---

## Description

Annual plant recruitment observed in a forest stand

## Usage

```
recruitment(forest, SpParams, control, minMonthTemp, moistureIndex)
```

## Arguments

| | |
|---|---|
| forest | An object of class forest. |
| SpParams | A data frame with species parameters (see SpParamsMED and SpParamsDefinition). |
| control | A list with default control parameters (see defaultControl). |
| minMonthTemp | Minimum month temperature. |
| moistureIndex | Moisture index (annual precipitation over annual potential evapotranspiration). |

## Details

Species can recruit if adults (sufficiently tall individuals) are present (seed rain can also be specified in a control parameter). Minimum month temperature and moisture index values are used to determine if recruitment was successful. Species also require a minimum amount of light at the ground level.

## Value

An object of class forest with the new plant cohorts.

## Author(s)

Miquel De Cáceres Ainsa, CREAF

## See Also

fordyn

## Examples

```
#Load example plot plant data
data(exampleforestMED)

#Default species parameterization
data(SpParamsMED)

#Initialize control parameters
control = defaultControl("Granier")

#Recruitment limits
plant_parameter(exampleforestMED, SpParamsMED, "MinTempRecr")
plant_parameter(exampleforestMED, SpParamsMED, "MinMoistureRecr")

#Compare recruitment outcomes
recruitment(exampleforestMED, SpParamsMED, control, 0, 0.25)
recruitment(exampleforestMED, SpParamsMED, control, 3, 0.25)
```

## resetInputs *Reset simulation inputs*

### Description

Function `resetInputs()` allows resetting state variables in `x` to their defaults.

### Usage

```
resetInputs(x)
```

### Arguments

| | |
|---|---|
| `x` | An object of class `spwbInput` or `growthInput`. |

### Value

Does not return any value. Instead, it modifies input object `x`.

### Author(s)

Miquel De Cáceres Ainsa, CREAF

### See Also

`spwbInput`, `growthInput`, `spwb`

## resistances *Soil-plant resistances*

### Description

Calculates and draws rhizosphere, root, stem and leaf resistances for simulation time steps

### Usage

```
resistances(x, cohort, relative = FALSE, draw = FALSE,
            cumulative = FALSE, xlab = NULL, ylab = NULL)
```

### Arguments

| | |
|---|---|
| x | An object of class spwb, pwb, growth or fordyn. The function only works with the result of simulations with transpirationMode = "Sperry". |
| cohort | An string indicating the cohort for which resistances are desired. |
| relative | A boolean flag to indicate that relative percentages are desired as output |
| draw | A boolean flag to indicate that a plot should be drawn. |
| cumulative | A flag to indicate that drawn series should be cumulative. |
| xlab | x-axis label. |
| ylab | y-axis label. |

### Details

The function makes internal calls to hydraulics_soilPlantResistances.

### Value

A data frame with dates in rows and resistance segments in columns (Rhizosphere, Root, Stem and Leaf). Values depend on whether relative = TRUE (percentages) or relative = FALSE (absolute resistance values). If draw = TRUE then a plot object is returned.

### Author(s)

Miquel De Cáceres Ainsa, CREAF

waterUseEfficiency, droughtStress

---

## root *Root functions*

---

### Description

Functions to calculate properties of fine/coarse roots within the soil, given root system parameters and soil layer definition.

### Usage

```
root_conicDistribution(Zcone, d)
root_ldrDistribution(Z50, Z95, d)
root_coarseRootLengths(v, d, depthWidthRatio = 1.0)
root_coarseRootLengthsFromVolume(VolInd, v, d, rfc)
root_coarseRootSoilVolume(v, d, depthWidthRatio = 1.0)
root_coarseRootSoilVolumeFromConductance(Kmax_rootxylem, VCroot_kmax, Al2As,
                                         v, d, rfc)
```

```
root_fineRootRadius(specificRootLength, rootTissueDensity)
root_fineRootHalfDistance(rootLengthDensity)
root_fineRootAreaIndex(Ksoil, krhizo, lai,
                       specificRootLength, rootTissueDensity,
                       rootLengthDensity)
root_fineRootBiomass(Ksoil, krhizo, lai, N,
                     specificRootLength, rootTissueDensity, rootLengthDensity)
root_rhizosphereMaximumConductance(Ksoil, fineRootBiomass, lai, N,
                                   specificRootLength, rootTissueDensity,
                                   rootLengthDensity)
root_fineRootSoilVolume(fineRootBiomass, specificRootLength, rootLengthDensity)
root_specificRootSurfaceArea(specificRootLength, rootTissueDensity)
root_individualRootedGroundArea(VolInd, V, d, rfc)
root_horizontalProportions(poolProportions, VolInd, N, V, d, rfc)
```

## Arguments

| | |
|---|---|
| Z50 | A vector of depths (in mm) corresponding to 50% of roots. |
| Z95 | A vector of depths (in mm) corresponding to 95% of roots. |
| Zcone | A vector of depths (in mm) corresponding to the root cone tip. |
| d | The width (in mm) corresponding to each soil layer. |
| v | Vector of proportions of fine roots in each soil layer. |
| depthWidthRatio | Ratio between radius of the soil layer with the largest radius and maximum rooting depth. |
| rfc | Percentage of rock fragment content (volume basis) for each layer. |
| Kmax_rootxylem | Sapwood-specific hydraulic conductivity of root xylem (in kg H2O·s-1·m-1·MPa-1). |
| VCroot_kmax | Root xylem maximum conductance per leaf area (mmol·m-2·s-1·MPa-1). |
| Al2As | Leaf area to sapwood area ratio (in m2·m-2). |
| specificRootLength | Specific fine root length (length of fine roots over weight). |
| rootTissueDensity | Fine root tissue density (weight over volume at turgidity). |
| Ksoil | Soil saturated conductivity (mmol·m-1·s-1·MPa-1). |
| krhizo | Rhizosphere maximum conductance per leaf area (mmol·m-2·s-1·MPa-1). |
| lai | Leaf area index. |
| rootLengthDensity | Fine root length density (length of fine roots over soil volume; cm/cm3) |
| fineRootBiomass | Biomass of fine roots (g). |
| V | Matrix of proportions of fine roots (cohorts x soil layers). |
| VolInd | Volume of soil (in m3) occupied by coarse roots per individual. |
| N | Density of individuals per hectare. |
| poolProportions | Division of the stand area among plant cohorts (proportions). |

## Details

- `root_conicDistribution()` assumes a (vertical) conic distribution of fine roots, whereas `root_ldrDistribution()` distributes fine roots according to the linear dose response model of Schenck & Jackson (2002). Return a matrix of fine root proportions in each layer with as many rows as elements in `Z` (or `Z50`) and as many columns as soil layers.
- `root_coarseRootLengths()` and `root_coarseRootLengthsFromVolume()` estimate the length of coarse roots (mm) for each soil layer, including axial and radial lengths.
- `root_coarseRootSoilVolume` estimates the soil volume (m3) occupied by coarse roots of an individual.
- `root_coarseRootSoilVolumeFromConductance` estimates the soil volume (m3) occupied by coarse roots of an individual from root xylem conductance.
- `root_fineRootHalfDistance()` calculates the half distance (cm) between neighbouring fine roots.
- `root_fineRootRadius()` calculates the radius of fine roots (cm).
- `root_fineRootAreaIndex()` estimates the fine root area index for a given soil conductivity and maximum rhizosphere conductance.
- `root_fineRootBiomass()` estimates the biomass of fine roots (g dry/individual) for a given soil conductivity and maximum rhizosphere conductance.
- `root_rhizosphereMaximumConductance()` is the inverse of the preceeding function, i.e. it estimates rhizosphere conductance from soil conductivity and fine root biomass.
- `root_fineRootSoilVolume()` calculates the soil volume (m3) occupied with fine roots.
- `root_specificRootSurfaceArea()` returns the specific fine root area (cm2/g).
- `root_individualRootedGroundArea()` calculates the area (m2) covered by roots of an individual, for each soil layer.
- `root_horizontalProportions()` calculates the (horizontal) proportion of roots of each cohort in the water pool corresponding to itself and that of other cohorts, for each soil layer. Returns a list (with as many elements as cohorts) with each element being a matrix.

```

## Arguments

| | |
|---|---|
| psiSoil | Soil water potential (in MPa). A scalar or a vector depending on the function. |
| psiRhizo | Water potential (in MPa) in the rhizosphere (root surface). |
| psiStem | Water potential (in MPa) in the stem. |
| psiLeaf | Water potential (in MPa) in the leaf. |
| PLCstem | Percent loss of conductance (in %) in the stem. |
| L | Vector with the length of coarse roots (mm) for each soil layer. |
| V | Vector with the proportion [0-1] of fine roots within each soil layer. |
| krhizomax | Maximum rhizosphere hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| kleafmax | Maximum leaf hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| kstemmax | Maximum stem xylem hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| krootmax | Maximum root xylem hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| psiStep | Water potential precision (in MPa). |
| rootc, rootd | Parameters of the Weibull function for roots (root xylem vulnerability curve). |
| stemc, stemd | Parameters of the Weibull function for stems (stem xylem vulnerability curve). |
| leafc, leafd | Parameters of the Weibull function for leaves (leaf vulnerability curve). |
| n, alpha | Parameters of the Van Genuchten function (rhizosphere vulnerability curve). |
| averageResistancePercent | Average (across water potential values) resistance percent of the rhizosphere, with respect to total resistance (rhizosphere + root xylem + stem xylem). |
| initialValue | Initial value of rhizosphere conductance. |
| xylemConductivity | Xylem conductivity as flow per length of conduit and pressure drop (in kg·m-1·s-1·MPa-1). |
| Al2As | Leaf area to sapwood area (in m2·m-2). |
| height | Plant height (in cm). |
| refheight | Reference plant height of measurement of xylem conductivity (in cm). |
| taper | A boolean flag to indicate correction by taper of xylem conduits (Christoffersen et al. 2017). |

## Details

Details of the hydraulic model are given in a vignette.

## Value

Values returned for each function are:

- `hydraulics_maximumSoilPlantConductance`: The maximum soil-plant conductance, in the same units as the input segment conductances.
- `hydraulics_averageRhizosphereResistancePercent`: The average percentage of resistance due to the rhizosphere, calculated across water potential values.
- `hydraulics_findRhizosphereMaximumConductance`: The maximum rhizosphere conductance value given an average rhizosphere resistance and the vulnerability curves of rhizosphere, root and stem elements.
- `hydraulics_taperFactorSavage`: Taper factor according to Savage et al. (2010).

SFM_metric *Standard fuel models (Albini 1976, Scott & Burgan 2005)*

## Description

Standard fuel models converted to metric system. Copied from package 'Rothermel' (Giorgio Vacchiano, Davide Ascoli).

## Usage

```
data("SFM_metric")
```

## Format

A data frame including standard fuel models as in Albini (1976) and Scott and Burgan (2005), to be used as input of `fire_Rothermel` function. All values converted to metric format.

`Fuel_Model_Type` A factor with levels `D` (for dynamic) or `S` (for static).

`Load_1h` Loading of 1h fuel class [t/ha].

`Load_10h` Loading of 10h fuel class [t/ha].

`Load_100h` Loading of 100h fuel class [t/ha]

`Load_Live_Herb` Loading of herbaceous fuels [t/ha]

`Load_Live_Woody` Loading of woody fuels [t/ha]

'`SA/V_1h`' Surface area to volume ratio of 1h fuel class [m2/m3]

'`SA/V_10h`' Surface area to volume ratio of 10h fuel class [m2/m3]

'`SA/V_100h`' Surface area to volume ratio of 100h fuel class [m2/m3]

'`SA/V_Live_Herb`' Surface area to volume ratio of herbaceous fuels [m2/m3]

'`SA/V_Live_Woody`' Surface area to volume ratio of woody fuels [m2/m3]

`Fuel_Bed_Depth` Fuel bed depth [cm]

`Mx_dead` Dead fuel moisture of extinction [percent]

`Heat_1h` Heat content of 1h fuel class [kJ/kg]

`Heat_10h` Heat content of 10h fuel class [kJ/kg]

`Heat_100h` Heat content of 100h fuel class [kJ/kg]

`Heat_Live_Herb` Heat content of herbaceous fuels [kJ/kg]

`Heat_Live_Woody` Heat content of woody fuels [kJ/kg]

shinyplot *Shiny app with interactive plots*

---

## Description

Creates a shiny app with interactive plots for simulation results and evaluation

## Usage

```
## S3 method for class 'spwb'
shinyplot(x, measuredData = NULL, ...)
## S3 method for class 'pwb'
shinyplot(x, measuredData = NULL, ...)
## S3 method for class 'growth'
shinyplot(x, measuredData = NULL, ...)
## S3 method for class 'fordyn'
shinyplot(x, measuredData = NULL, ...)
## S3 method for class 'spwb_day'
shinyplot(x, ...)
## S3 method for class 'pwb_day'
shinyplot(x, ...)
## S3 method for class 'growth_day'
shinyplot(x, ...)
```

## Arguments

| | |
|---|---|
| x | An object of the right class. |
| measuredData | A data frame with observed/measured values (see evaluation_plot). |
| ... | Additional parameters. |

## Details

Only run this function in interactive mode. When measuredData is not NULL, an additional panel is shown for evaluation plots.

## Value

An object that represents the shiny app

## Author(s)

Miquel De Cáceres Ainsa, CREAF

## See Also

plot.spwb, evaluation_plot

## Examples

```
## Only run this example in interactive R sessions
## Not run:
#Load example daily meteorological data
data(examplemeteo)

#Load example plot plant data
data(exampleforestMED)

#Default species parameterization
data(SpParamsMED)

#Initialize soil with default soil params (4 layers)
examplesoil = soil(defaultSoilParams(4))

#Initialize control parameters
control = defaultControl("Granier")

#Initialize input
x1 = forest2spwbInput(exampleforestMED, examplesoil, SpParamsMED, control)

#Call simulation function
S1<-spwb(x1, examplemeteo, latitude = 41.82592, elevation = 100)

#Load observed data (in this case the same simulation results with some added error)
data(exampleobs)

#Call interactive plot shiny app
shinyplot(S1, exampleobs)

## End(Not run)
```

---

# soil *Soil initialization*

---

## Description

Initializes soil parameters and state variables for its use in simulations.

## Usage

```
soil(SoilParams, VG_PTF = "Toth", W = as.numeric(c(1)), SWE = 0)
## S3 method for class 'soil'
print(x, model="SX", ...)
redefineSoilLayers(SoilParams, widths = c(300, 700, 1000, 2000))
```

## Arguments

| | |
|---|---|
| SoilParams | A data frame of soil parameters (see an example in defaultSoilParams). |
| VG_PTF | Pedotransfer functions to obtain parameters for the van Genuchten-Mualem equations. Either "Carsel" (Carsel and Parrish 1988) or "Toth" (Toth et al. 2015). |
| W | A numerical vector with the initial relative water content of each soil layer. |
| SWE | Initial snow water equivalent of the snow pack on the soil surface (mm). |
| x | An object of class soil. |
| model | Either 'SX' or 'VG' for Saxton or Van Genuchten pedotransfer models. |
| widths | A numeric vector indicating the desired layer widths, in *mm*. |
| ... | Additional parameters to print. |

## Details

Function print prompts a description of soil characteristics and state variables (water content and temperature) according to a water retention curve (either Saxton's or Van Genuchten's). Volume at field capacity is calculated assuming a soil water potential equal to -0.033 MPa. Parameter Temp is initialized as missing for all soil layers. Function redefineSoilLayers allows redefining soil layer widths of an input data frame of soil parameters.

## Value

Function soil returns a list of class soil with the following elements:

- SoilDepth: Soil depth (in mm).
- W: State variable with relative water content of each layer (in as proportion relative to FC).
- Temp: State variable with temperature (in ºC) of each layer.
- Ksoil: Kappa parameter for infiltration.
- Gsoil: Gamma parameter for infiltration.
- dVec: Width of soil layers (in mm).
- sand: Sand percentage for each layer (in percent volume).
- clay: Clay percentage for each layer (in percent volume).
- om: Organic matter percentage for each layer (in percent volume).
- VG_alpha, VG_n, VG_theta_res, VG_theta_sat: Parameters for van Genuchten's pedotransfer functions, for each layer, corresponding to the USDA texture type.
- Ksat: Saturated soil conductivity for each layer (estimated using function soil_saturatedConductivitySX.
- macro: Macroporosity for each layer (estimated using Stolf et al. 2011).

- `rfc`: Percentage of rock fragment content for each layer.
- `Kdrain`: Saturated vertical hydraulic conductivity (mm/day) (i.e. how easy is deep drainage towards groundwater). Function `soil` estimates it as a function of soil saturated hydraulic conductivity, but should be parametrized as a function of bedrock material.

---

`soil hydrology` *Soil infiltration and bare soil evaporation*

---

## Description

Function `hydrology_infiltrationAmount` calculates the amount of water that infiltrates into the topsoil, according to the USDA SCS curve number method (Boughton 1989). The remaining is assumed to be lost as surface runoff. Function `hydrology_soilEvaporationAmount` calculates the amount of evaporation from bare soil, following Ritchie (1972). Function `hydrology_snowMelt` calculates the maximum amount of snowmelt according to Kergoat (1998).

## Usage

```
hydrology_infiltrationAmount(input, Ssoil)
hydrology_infiltrationRepartition(I, dVec, macro, a = -0.005, b = 3)
hydrology_soilEvaporationAmount(DEF,PETs, Gsoil)
hydrology_soilEvaporation(soil, soilFunctions, pet, LgroundSWR, modifySoil = TRUE)
hydrology_snowMelt(tday, rad, LgroundSWR, elevation)
```

## Arguments

| | |
|---|---|
| input | A numeric vector of (daily) water input (in mm of water). |
| Ssoil | Soil water storage capacity (can be referred to topsoil) (in mm of water). |
| DEF | Water deficit in the (topsoil) layer. |
| PETs | Potential evapotranspiration at the soil surface. |
| Gsoil | Gamma parameter (maximum daily evaporation). |
| I | Soil infiltration (in mm of water). |
| dVec | Width of soil layers (in mm). |
| macro | Macroporosity of soil layers (in %). |
| soil | An object of class soil. |
| soilFunctions | Soil water retention curve and conductivity functions, either 'SX' (for Saxton) or 'VG' (for Van Genuchten). |
| pet | Potential evapotranspiration for a given day (mm) |
| LgroundSWR | Percentage of short-wave radiation (SWR) reaching the ground. |
| modifySoil | Boolean flag to indicate that the input soil object should be modified during the simulation. |
| tday | Average day temperature (ºC). |
| rad | Solar radiation (in MJ/m2/day). |
| elevation | Altitude above sea level (m). |
| a,b | Parameters of the extinction function used for water infitration. |

## Details

See description of infiltration and soil evaporation processes in De Caceres et al. (2015).

## Value

Function hydrology_infiltrationAmount a vector of the same length as input containing the daily amount of water that infiltrates into the soil (in mm of water). Function hydrology_infiltrationRepartition estimates the amount of infiltrated water that reaches each soil layer. Function hydrology_soilEvaporationAmount returns the amount of water evaporated from the soil. Function hydrology_soilEvaporation returns a vector of water evaporated from each soil layer.

soil_retentionCurvePlot(soil, model="SX", layer = 1,
                        psi = seq(0, -6.0, by=-0.01),
                        relative = TRUE, to = "SAT")
```

## Arguments

| | |
|---|---|
| clay | Percentage of clay (in percent weight). |
| sand | Percentage of sand (in percent weight). |
| n, alpha, theta_res, theta_sat | Parameters of the Van Genuchten-Mualem model (m = 1 - 1/n). |
| psi | Water potential (in MPa). |
| theta | Relative water content (in percent volume). |
| om | Percentage of organic matter (optional, in percent weight). |
| mmol | Boolean flag to indicate that saturated conductivity units should be returned in mmol/m/s/MPa. If mmol = FALSE then units are cm/day. |
| bd | Bulk density (in g/cm3). |
| topsoil | A boolean flag to indicate topsoil layer. |
| soilType | A string indicating the soil type. |
| soil | Soil object (returned by function soil). |
| model | Either 'SX' or 'VG' for Saxton's or Van Genuchten's water retention models; or 'both' to plot both retention models. |
| layer | Soil layer to be plotted. |
| relative | Boolean flag to indicate that retention curve should be relative to field capacity or saturation. |
| to | Either 'SAT' (saturation) or 'FC' (field capacity). |
| minPsi | Minimum water potential (in MPa) to calculate the amount of extractable water. |
| pWeight | Percentage of corresponding to rocks, in weight. |
| bulkDensity | Bulk density of the soil fraction (g/cm3). |
| rockDensity | Rock density (g/cm3). |

## Details

- soil_psi2thetaSX() and soil_theta2psiSX() calculate water potentials (MPa) and water contents (theta) using texture data the formulae of Saxton et al. (1986) or Saxton & Rawls (2006) depending on whether organic matter is available.
- soil_psi2thetaVG() and soil_theta2psiVG() to the same calculations as before, but using the Van Genuchten - Mualem equations (Wösten & van Genuchten 1988).
- soil_saturatedConductivitySX() returns the saturated conductivity of the soil (in cm/day or mmol/m/s/MPa), estimated from formulae of Saxton et al. (1986) or Saxton & Rawls (2006) depending on whether organic matter is available.

- `soil_unsaturatedConductivitySX()` returns the unsaturated conductivity of the soil (in cm/day or mmol/m/s/MPa), estimated from formulae of Saxton et al. (1986) or Saxton & Rawls (2006) depending on whether organic matter is available.
- `soil_USDAType()` returns the USDA type (a string) for a given texture.
- `soil_vanGenuchtenParamsCarsel()` gives parameters for van Genuchten-Mualem equations (alpha, n, theta_res and theta_sat, where alpha is in MPa-1) for a given texture type (Leij et al. 1996)
- `soil_vanGenuchtenParamsToth()` gives parameters for van Genuchten-Mualem equations (alpha, n, theta_res and theta_sat, where alpha is in MPa-1) for a given texture, organic matter and bulk density (Toth et al. 2015).
- `soil_psi()` returns the water potential (MPa) of each soil layer, according to its water retention model.
- `soil_theta()` returns the moisture content (as percent of soil volume) of each soil layer, according to its water retention model.
- `soil_water()` returns the water volume (mm) of each soil layer, according to its water retention model.
- `soil_conductivity()` returns the conductivity of each soil layer (mmol/m/s/MPa), according the Saxton model.
- `soil_waterExtractable()` returns the water volume (mm) extractable from the soil according to its water retention curves and up to a given soil water potential.
- `soil_waterFC()` and `soil_thetaFC()` calculate the water volume (in mm) and moisture content (as percent of soil volume) of each soil layer at field capacity, respectively.
- `soil_waterWP()` and `soil_thetaWP()` calculate the water volume (in mm) and moisture content (as percent of soil volume) of each soil layer at wilting point (-1.5 MPa), respectively.
- `soil_waterSAT()`, `soil_thetaSATSX()` and `soil_thetaSAT()` calculate the saturated water volume (in mm) and moisture content (as percent of soil volume) of each soil layer.
- `soil_waterTableDepth()` returns water table depth in mm from surface.
- `soil_rockWeight2Volume()` transforms rock percentage from weight to volume basis.
- `soil_retentionCurvePlot()` allows ploting the water retention curve of a given soil layer.

## Value

Depends on the function (see details).

---

# soil thermodynamics *Soil thermodynamic functions*

---

## Description

Functions `soil_thermalConductivity` and `soil_thermalCapacity` calculate thermal conductivity and thermal capacity for each soil layer, given its texture and water content. Functions `soil_temperatureGradient` and `soil_temperatureChange` are used to calculate soil temperature gradients (in ºC/m) and temporal temperature change (in ºC/s) given soil layer texture and water content (and possibly including heat flux from above).

## Usage

```
soil_thermalConductivity(soil, model = "SX")
soil_thermalCapacity(soil, model = "SX")
soil_temperatureChange(dVec, Temp, sand, clay, W, Theta_FC, Gdown)
soil_temperatureGradient(dVec, Temp)
```

## Arguments

| | |
|---|---|
| soil | Soil object (returned by function soil). |
| model | Either 'SX' or 'VG' for Saxton's or Van Genuchten's pedotransfer models. |
| dVec | Width of soil layers (in mm). |
| Temp | Temperature (in ºC) for each soil layer. |
| clay | Percentage of clay (in percent weight) for each layer. |
| sand | Percentage of sand (in percent weight) for each layer. |
| W | Soil moisture (in percent of field capacity) for each layer. |
| Theta_FC | Relative water content (in percent volume) at field capacity for each layer. |
| Gdown | Downward heat flux from canopy to soil (in W·m-2). |

## Value

Function soil_thermalConductivity returns a vector with values of thermal conductivity (W/m/ºK) for each soil layer. Function soil_thermalCapacity returns a vector with values of heat storage capacity (J/m3/ºK) for each soil layer. Function soil_temperatureGradient returns a vector with values of temperature gradient between consecutive soil layers. Function soil_temperatureChange returns a vector with values of instantaneous temperature change (ºC/s) for each soil layer.

soil_thermalConductivity(examplesoil)
soil_thermalCapacity(examplesoil)
```

`Species values` *Species description functions*

## Description

Functions to calculate attributes of a `forest` object by species or to extract species parameters from a species parameter table (`SpParamsMED`).

## Usage

```
species_basalArea(x, SpParams)
species_cover(x, SpParams, mode = "MED")
species_density(x, SpParams, mode = "MED")
species_foliarBiomass(x, SpParams, gdd = NA, mode = "MED")
species_fuel(x, SpParams, gdd = NA, includeDead = TRUE, mode = "MED")
species_LAI(x, SpParams, gdd = NA, mode = "MED")
species_phytovolume(x, SpParams)
species_parameter(SP, SpParams, parName, fillMissing = TRUE)
species_characterParameter(SP, SpParams, parName)
```

## Arguments

| | |
|---|---|
| `x` | An object of class `forest`. |
| `SpParams` | A data frame with species parameters (see `SpParamsMED`). |
| `gdd` | Growth degree days (to account for leaf phenology effects). |
| `includeDead` | A flag to indicate that standing dead fuels (dead branches) are included. |
| `mode` | Calculation mode, either "MED" or "US". |
| `SP` | An integer vector of species codes. |
| `parName` | A string with a parameter name. |
| `fillMissing` | A boolean flag to try imputation on missing values. |

## Value

A vector with values for each species in `SpParams`:

- `species_basalArea`: Species basal area (m2/ha).
- `species_cover`: Shrub cover (in percent).
- `species_density`: Plant density (ind/ha). Tree density is directly taken from the forest object, while the shrub density is estimated from cover and height by calculating the area of a single individual.
- `species_foliarBiomass`: Standing biomass of leaves (in kg/m2).
- `species_fuel`: Fine fuel load (in kg/m2).
- `species_LAI`: Leaf area index (m2/m2).

- species_phytovolume: Shrub phytovolume (m3/m2).
- species_parameter: A numeric vector with the parameter values of each input species.
- species_characterParameter: A character vector with the parameter values of each input species.

```

---

# SpParams *Data tables with species parameter definition and values for Mediterranean and US*

---

## Description

A data sets of species parameter definition and values, the latter resulting from existing databases, fit to empirical data or expert-based guesses.

## Usage

```
data("SpParamsDefinition")
data("SpParamsMED")
data("SpParamsUS")
```

## Format

Data frame SpParamsDefinition has parameters in rows and columns 'ParameterName', 'ParameterGroup', 'Definition', 'Type' and 'Units'. Data frames SpParamsMED and SpParamsUS have species or genus as rows and column names equal to parameter names in SpParamsDefinition.

## Details

Plant trait parameter sources are listed in the bibliography section. Details of the procedures used to obtain the species parameter tables can be found in the article 'Species parameterization for Spain' at https://emf-creaf.github.io/medfate/.

spwb *Soil-plant water balance*

---

## Description

Function spwb() is a water balance model that determines changes in soil moisture, soil water potentials, plant transpiration and drought stress at daily steps for a given forest stand during a period specified in the input climatic data. Function pwb() performs plant water balance only (i.e. soil moisture dynamics is an input) at daily steps for a given forest stand during a period specified in the input climatic data. On both simulation functions plant transpiration and photosynthesis processes are conducted with different level of detail depending on the transpiration mode.

## Usage

```
spwb(x, meteo,  latitude , elevation = NA, slope = NA, aspect = NA,
     CO2ByYear = numeric(0))
pwb(x, meteo, W, latitude, elevation = NA, slope = NA, aspect = NA,
    canopyEvaporation = numeric(0), snowMelt = numeric(0),
    soilEvaporation = numeric(0), CO2ByYear = numeric(0))
```

## Arguments

| | |
|---|---|
| x | An object of class spwbInput. |
| meteo | A data frame with daily meteorological data series. Row names of the data frame should correspond to date strings with format "yyyy-mm-dd" (see Date). The following columns are required:<br>• MinTemperature: Minimum temperature (in degrees Celsius).<br>• MaxTemperature: Maximum temperature (in degrees Celsius).<br>• MinRelativeHumidity: Minimum relative humidity (in percent).<br>• MaxRelativeHumidity: Maximum relative humidity (in percent).<br>• Precipitation: Precipitation (in mm).<br>• Radiation: Solar radiation (in MJ/m2/day), required only if snowpack = TRUE.<br>• WindSpeed: Wind speed (in m/s). If not available, this column can be left with NA values.<br>• CO2: Atmospheric (abovecanopy) CO2 concentration (in ppm). This column may not exist, or can be left with NA values. In both cases simulations will assume a constant value specified in defaultControl. |
| W | A matrix with the same number of rows as meteo and as many columns as soil layers, containing the soil moisture of each layer as proportion of field capacity. |
| latitude | Latitude (in degrees). |
| elevation, slope, aspect | Elevation above sea level (in m), slope (in degrees) and aspect (in degrees from North). Required when using the 'Sperry' transpiration mode. Elevation is also required for 'Granier' if snowpack dynamics are simulated. |
| CO2ByYear | A named numeric vector with years as names and atmospheric CO2 concentration (in ppm) as values. Used to specify annual changes in CO2 concentration along the simulation (as an alternative to specifying daily values in meteo). |
| canopyEvaporation | A vector of daily canopy evaporation (from interception) values (mm). The length should match the number of rows in meteo. |
| soilEvaporation | A vector of daily bare soil evaporation values (mm). The length should match the number of rows in meteo. |
| snowMelt | A vector of daily snow melt values (mm). The length should match the number of rows in meteo. |

## Details

The model using 'Granier' transpiration mode is illustrated by function transp_transpirationGranier and described in De Caceres et al. (2015). Simulations using the 'Sperry' transpiration mode are computationally much more expensive, are described in De Cáceres et al. (2021) and are illustrated by function transp_transpirationSperry.

## Value

Function spwb returns a list of class 'spwb' whereas Function pwb returns a list of class 'pwb'. There are many elements in common in these lists, so they are listed here together:

- "latitude": Latitude (in degrees) given as input.
- "topography": Vector with elevation, slope and aspect given as input.
- "weather": A copy of the input weather data frame.
- "spwbInput": An copy of the object x of class spwbInput given as input.
- "spwbOutput": An copy of the final state of the object x of class spwbInput.
- "WaterBalance": A data frame where different variables (in columns) are given for each simulated day (in rows):
  - "PET": Potential evapotranspiration (in mm).
  - "Precipitation": Input precipitation (in mm).
  - "Rain": Precipitation as rain (in mm).
  - "Snow": Precipitation as snow (in mm).
  - "NetRain": Net rain, after accounting for interception (in mm).
  - "Infiltration": The amount of water infiltrating into the soil (in mm).
  - "Runoff": The amount of water exported via surface runoff (in mm).
  - "DeepDrainage": The amount of water exported via deep drainage (in mm).
  - "Evapotranspiration": Evapotranspiration (in mm).
  - "SoilEvaporation": Bare soil evaporation (in mm).
  - "PlantExtraction": Amount of water extracted from soil by plants (in mm) (can only be different from transpiration for transpirationMode = "Sperry" when capacitance is considered).
  - "Transpiration": Plant transpiration (considering all soil layers) (in mm).
  - "HydraulicRedistribution": Water redistributed among soil layers, transported through the plant hydraulic network (only for transpirationMode = "Sperry").
- "EnergyBalance": A data frame with the daily values of energy balance components for the soil and the canopy (only for transpirationMode = "Sperry").
- "Temperature": A data frame with the daily values of minimum/mean/maximum temperatures for the atmosphere (input), canopy and soil (only for transpirationMode = "Sperry").
- "Soil": A data frame where different variables (in columns) are given for each simulated day (in rows):
  - "W.1", ..., "W.k": Relative soil moisture content (relative to field capacity) in each soil layer.
  - "ML.1", ..., "ML.k": Soil water volume in each soil layer (in L/m2).
  - "MLTot": Total soil water volume (in L/m2).
  - "SWE": Snow water equivalent (mm) of the snow pack.
  - "PlantExt.1", ..., "PlantExt.k": Plant extraction from each soil layer (in mm).
  - "HydraulicInput.1", ..., "HydraulicInput.k": Water that entered the layer coming from other layers and transported via the plant hydraulic network (in mm) (only for transpirationMode = "Sperry").

  - "psi.1", ..., "psi.k": Soil water potential in each soil layer (in MPa).
- "Stand": A data frame where different variables (in columns) are given for each simulated day (in rows):
  - "LAI": LAI of the stand (including live and dead leaves) (in m2/m2).
  - "LAIlive": LAI of the stand assuming all leaves are unfolded (in m2/m2).
  - "LAIexpanded": LAI of the stand of leaves actually unfolded (in m2/m2).
  - "LAIdead": LAI of the stand corresponding to dead leaves (in m2/m2).
  - "Cm": Water retention capacity of the canopy (in mm) (accounting for leaf phenology).
  - "LgroundPAR": The percentage of PAR that reaches the ground (accounting for leaf phenology).
  - "LgroundSWR": The percentage of SWR that reaches the ground (accounting for leaf phenology).
- "Plants": A list of daily results for plant cohorts (see below).
- "subdaily": A list of objects of class spwb_day, one per day simulated (only if required in control parameters, see defaultControl).

When transpirationMode = "Granier", element "Plants" is a list with the following subelements:

- "LAI": A data frame with the daily leaf area index for each plant cohort.
- "LAIlive": A data frame with the daily leaf area index for each plant cohort, assuming all leaves are unfolded (in m2/m2).
- "FPAR": A data frame with the fraction of PAR at the canopy level of each plant cohort.
- "AbsorbedSWRFraction": A data frame with the fraction of SWR absorbed by each plant cohort.
- "Transpiration": A data frame with the amount of daily transpiration (in mm) for each plant cohort.
- "GrossPhotosynthesis": A data frame with the amount of daily gross photosynthesis (in g C·m-2) for each plant cohort.
- "PlantPsi": A data frame with the average daily water potential of each plant (in MPa).
- "StemPLC": A data frame with the average daily proportion of stem conductance loss of each plant ([0-1]).
- "PlantWaterBalance": A data frame with the daily balance between transpiration and soil water extraction for each plant cohort.
- "LeafRWC": A data frame with the average daily leaf relative water content of each plant (in percent).
- "StemRWC": A data frame with the average daily stem relative water content of each plant (in percent).
- "LFMC": A data frame with the daily live fuel moisture content (in percent of dry weight).
- "PlantStress": A data frame with the amount of daily stress [0-1] suffered by each plant cohort (relative whole-plant conductance).

If transpirationMode="Sperry", element "Plants" is a list with the following subelements:

- "LAI": A data frame with the daily leaf area index for each plant cohort.
- "AbsorbedSWR": A data frame with the daily SWR absorbed by each plant cohort.
- "NetLWR": A data frame with the daily net LWR by each plant cohort.
- "Transpiration": A data frame with the amount of daily transpiration (in mm) for each plant cohorts.
- "GrossPhotosynthesis": A data frame with the amount of daily gross photosynthesis (in g C·m-2) for each plant cohort.
- "NetPhotosynthesis": A data frame with the amount of daily net photosynthesis (in g C·m-2) for each plant cohort.
- "dEdP": A data frame with mean daily values of soil-plant conductance (derivative of the supply function) for each plant cohort.
- "PlantWaterBalance": A data frame with the daily balance between transpiration and soil water extraction for each plant cohort.
- "SunlitLeaves" and "ShadeLeaves": A list with daily results for sunlit and shade leaves:
  - "PsiMin": A data frame with the minimum (midday) daily sunlit or shade leaf water potential (in MPa).
  - "PsiMax": A data frame with the maximum (predawn) daily sunlit or shade leaf water potential (in MPa).
- "LeafPsiMin": A data frame with the minimum (midday) daily (average) leaf water potential of each plant (in MPa).
- "LeafPsiMax": A data frame with the maximum (predawn) daily (average) leaf water potential of each plant (in MPa).
- "LeafRWC": A data frame with the average daily leaf relative water content of each plant (in percent).
- "StemRWC": A data frame with the average daily stem relative water content of each plant (in percent).
- "LFMC": A data frame with the daily live fuel moisture content (in percent of dry weight).
- "StemPsi": A data frame with the minimum daily stem water potential of each plant (in MPa).
- "StemPLC": A data frame with the average daily proportion of stem conductance loss of each plant ([0-1]).
- "RootPsi": A data frame with the minimum daily root water potential of each plant (in MPa).
- "RhizoPsi": A list of data frames (one per plant cohort) with the minimum daily root water potential of each plant (in MPa).
- "PlantStress": A data frame with the amount of daily stress [0-1] suffered by each plant cohort (relative whole-plant conductance).

## End(Not run)
```

---

spwb_day *Single day simulation*

---

## Description

Function spwb_day performs water balance for a single day and growth_day performs water and carbon balance for a single day.

## Usage

```
spwb_day(x, date, tmin, tmax, rhmin, rhmax, rad, wind,
         latitude, elevation, slope, aspect, prec, CO2 = NA,
         runon = 0.0, modifyInput = TRUE)
growth_day(x, date, tmin, tmax, rhmin, rhmax, rad, wind,
           latitude, elevation, slope, aspect, prec, CO2 = NA,
           runon = 0.0, modifyInput = TRUE)
```

## Arguments

| | |
|---|---|
| x | An object of class spwbInput or growthInput. |
| date | Date as string "yyyy-mm-dd". |
| tmin, tmax | Minimum and maximum temperature (in degrees Celsius). |
| rhmin, rhmax | Minimum and maximum relative humidity (in percent). |
| rad | Solar radiation (in MJ/m2/day). |
| wind | Wind speed (in m/s). |
| prec | Precipitation (in mm). |
| latitude | Latitude (in degrees). Required when using the 'Sperry' transpiration mode. |
| elevation, slope, aspect | Elevation above sea level (in m), slope (in degrees) and aspect (in degrees from North). Required when using the 'Sperry' transpiration mode. |

| | |
|---|---|
| CO2 | Atmospheric CO2 concentration (in ppm). If missing, default value is drawn from control parameter 'defaultCO2' in x. |
| runon | Surface water amount running on the target area from upslope (in mm). |
| modifyInput | Boolean flag to indicate that the input x object is allowed to be modified during the simulation. |

## Details

Detailed model description is available in the vignettes section. The model using 'Granier' transpiration mode is described in De Caceres et al. (2015). Simulations using the 'Sperry' transpiration mode are computationally much more expensive, are described in De Cáceres et al. (2021) and are illustrated by function transp_transpirationSperry.

## Value

Function spwb_day() returns a list of class spwb_day with the following elements:

- "cohorts": A data frame with cohort information, copied from spwbInput.
- "topography": Vector with elevation, slope and aspect given as input.
- "weather": A vector with the input weather.
- "WaterBalance": A vector of water balance components (rain, snow, net rain, infiltration, ...) for the simulated day, equivalent to one row of 'WaterBalance' object given in spwb.
- "Soil": A data frame with results for each soil layer:
  - "SoilEvaporation": Water evaporated from the soil surface (in mm).
  - "HydraulicInput": Water entering each soil layer from other layers, transported via plant hydraulic network (in mm) (only for transpirationMode = "Sperry").
  - "HydraulicOutput": Water leaving each soil layer (going to other layers or the transpiration stream) (in mm) (only for transpirationMode = "Sperry").
  - "PlantExtraction": Water extracted by plants from each soil layer (in mm).
  - "psi": Soil water potential (in MPa).
- "Stand": A named vector with with stand values for the simulated day, equivalent to one row of 'Stand' object returned by spwb.
- "Plants": A data frame of results for each plant cohort (see transp_transpirationGranier or transp_transpirationSperry).

The following items are only returned when transpirationMode = "Sperry":

- "EnergyBalance": Energy balance of the stand (see transp_transpirationSperry).
- "RhizoPsi": Minimum water potential (in MPa) inside roots, after crossing rhizosphere, per cohort and soil layer.
- "SunlitLeaves" and "ShadeLeaves": For each leaf type, a data frame with values of LAI, Vmax298 and Jmax298 for leaves of this type in each plant cohort.
- "ExtractionInst": Water extracted by each plant cohort during each time step.
- "PlantsInst": A list with instantaneous (per time step) results for each plant cohort (see transp_transpirationSperry).

- "LightExtinction": A list of information regarding radiation balance through the canopy, as returned by function light_instantaneousLightExtinctionAbsortion.
- "CanopyTurbulence": Canopy turbulence (see wind_canopyTurbulence).

`spwb_ldrCalibration` *Calibration of root distribution*

---

## Description

The function `spwb_ldrCalibration` calibrates the species root distribution within `spwb`, given the arguments `x`, `meteo`, `psi_crit`, `obs` and `calibVar`. This calibration is based on reference measured values. These reference measured values can be `Soil water content`, `Total tranpiration` or `Transpiration` by `cohort`. Return the calibrated root distribution for each tree species (no shrub calibration is done), expressed as parameters of the function `root_ldrDistribution`.

## Usage

```
spwb_ldrCalibration(x, meteo, calibVar, obs,
                    RZmin = 301, RZmax = 4000,
                    V1min = 0.01, V1max = 0.94, resolution = 20, heat_stop = 0,
                    transformation = "identity", verbose = FALSE)
```

## Arguments

| | |
|---|---|
| `x` | An object of class `spwbInput`. |
| `meteo` | A data frame with daily meteorological data series. |
| `calibVar` | A character string indicating the calibration variable to be used. It can be one of the following: `SWC`, `Eplanttot` or `Cohorts`. |

| | |
|---|---|
| obs | Measured calibration variable. Depending on the value of calibVar it can be a numeric vector with the measured SWC values (if calibVar = "SWC"), or a data frame with the first column containing the measured total transpiration (named Eplanttot) and the following columns containing the cohorts transpiration. |
| RZmin | The minimum value of RZ (the rooting depth) to be explored (in mm) |
| RZmax | The maximum value of RZ (the rooting depth) to be explored (in mm) |
| V1min | The minimum value of V1 (the root proportion in the first soil layer) to be explored |
| V1max | The maximum value of V1 (the root proportion in the first soil layer) to be explored |
| resolution | An integer defining the number of values to obtain by discretization of the root parameters RZ and V1. The number of parameter combinations and therefore the computation cost increases increase with the square of resolution |
| transformation | Function to modify the size of Z intervals to be explored (by default, bins are equal). |
| heat_stop | An integer defining the number of days during to discard from the calculation of the optimal root distribution. Usefull if the soil water content initialization is not certain |
| verbose | A logical value. Print the internal messages of the function? |

## Details

This function performs three different kinds of calibration, selecting those root distribution parameters that minimize the MAE between the predicted values and the measured values provided in obs argument. If calibVar = "SWC" different V1 values are tested running spwb maintaining the total soil depth provided in x and assuming that value is also the depth containing 95 percent of the roots. If calibVar = "Eplanttot" or calibVar = 'Cohorts' different combinations of RZ and V1 values are tested for each tree cohort and the root paramters are selected based on the MAE between the total transpiration or the cohort transpiration.

## Value

THe function returns a data frame containing the species index used in medfate, calibrated values for Z50, Z95 and V1 and the MAE value for that combination.

spwb_ldrOptimization *Optimization of root distribution*

## Description

Functions spwb_ldrExploration and spwb_ldrOptimization are used to find optimum the species root distribution within spwb, given the arguments x, meteo and psi_crit.

## Usage

```
spwb_ldrExploration(x, meteo, cohorts = NULL,
                    RZmin = 301, RZmax = 4000,
                    V1min = 0.01, V1max = 0.94, resolution = 10, heat_stop = 0,
                    transformation = "identity",
                    verbose = FALSE, ...)
spwb_ldrOptimization(y, psi_crit, opt_mode = 1)
```

## Arguments

| | |
|---|---|
| x | An object of class spwbInput. |
| meteo | A data frame with daily meteorological data series (see spwb). |
| cohorts | A character string with the names of cohorts to be explored. If NULL then all cohorts are explored. |
| RZmin | The minimum value of RZ (the rooting depth) to be explored (in mm) |
| RZmax | The maximum value of RZ (the rooting depth) to be explored (in mm) |
| V1min | The minimum value of V1 (the root proportion in the first soil layer) to be explored |
| V1max | The maximum value of V1 (the root proportion in the first soil layer) to be explored |
| resolution | An integer defining the number of values to obtain by discretization of the root parameters RZ and V1. The number of parameter combinations and therefore the computation cost increases increase with the square of resolution |
| transformation | Function to modify the size of Z intervals to be explored (by default, bins are equal). |
| heat_stop | An integer defining the number of days during to discard from the calculation of the optimal root distribution. Usefull if the soil water content initialization is not certain |
| ... | Additional parameters to function spwb. |
| y | The result of calling spwb_ldrExploration. |
| psi_crit | A numerical vector of length iqual to the number of species in the plot containing the species values of water potential inducing hydraulic failure (in MPa). Use NA values to skip optimization for particular plant cohorts. |
| opt_mode | Optimization mode: |

- opt_mode = 1 maximizes transpiration along the line of stress equal to psi_crit (Cabon et al. 2018). The optimization is based on the eco-hydrological equilibrium hypothesis (Eagleson, 1982), which is formulated here as the root distribution for which plant transpiration is maximized while the plant water potential is close to the species-defined critical value psi_crit (Cabon et al.,2018).
- opt_mode = 2 maximizes transpiration among combinations with stress according to psi_crit).
- opt_mode = 3 maximizes photosynthesis among combinations with stress according to psi_crit).
- opt_mode = 4 maximizes transpiration, subject to root construction constrains, among combinations with stress according to psi_crit).
- opt_mode = 5 maximizes photosynthesis, subject to root construction constrains, among combinations with stress according to psi_crit).

verbose A logical value. Print the internal messages of the function?

## Details

For each combination of the parameters RZ and V1 the function spwb_ldrExploration runs spwb, setting the total soil depth equal to RZ. The root proportion in each soil layer is derived from V1, the depth of the first soil layer and RZ using the LDR root distribution model (Schenk and Jackson, 2002) and assuming that the depth containing 95 percent of the roots is equal to RZ. Function spwb_ldrOptimization takes the result of the exploration and tries to find optimum root distribution parameters. psi_crit, the species specific water potential inducing hydraulic failure, can be approached by the water potential inducing 50 percent of loss of conductance for the and gymnosperms and 88 percent for the angiosperms (Urli et al., 2013, Brodribb et al., 2010). Details of the hypothesis and limitations of the optimization method are given in Cabon et al. (2019).

## Value

Function spwb_ldrExploration returns a list containing a list containing the explored RZ and V1 combinations as well as arrays with the values of average daily plant transpiration, average daily net photosynthesis and the minimum plant water potential for each cohort and parameter combination.

Function spwb_ldrOptimization returns a data frame with containing the species index used in medfate, psi_crit and the optimized values of V1 and the LDR parameters Z50 and Z95 (see root_ldrDistribution) and as many rows as the number of species.

```

spwb_sensitivity *Sensitivity analysis for soil plant water balance simulations*

## Description

Performs a set of calls to spwb with the aim to determine the sensitivity to particular parameters.

## Usage

```
spwb_sensitivity(x, soil, meteo,
                 paramType = "above", paramName = "LAI_live", cohort = 1,
                 p_change = c(-80,-40,-20,0,20,40,80),
                 summary.fun = NULL, simplify=TRUE,...)
```

## Arguments

| | |
|---|---|
| x | An object of class spwbInput. |
| soil | A list containing the description of the soil (see soil). |
| meteo | A data frame with daily meteorological data series (see spwb). |
| paramType | Data frame of x to modify. |
| paramName | Name of the parameter to modify. |
| cohort | Integer with the cohort to modify. |
| p_change | Numerical vector with percentages of change. |
| summary.fun | Summary function to be applied to the results of each simulation. |
| simplify | Whether the result of summary.fun should be simplified (see sapply). |
| ... | Additional parameters to function spwb. |

## Details

Due to parameter dependence, modifying some parameters affects others:

- Setting paramName = "Z50/Z95" affects belowLayers$V, belowLayers$VCroot_kmax and belowLayers$VGrhizo_kmax.
- Modifying LAI_live also affects LAI_expanded.
- Modifying VCroot_kmax from paramsTranspiration affects both VCroot_kmax and belowLayers$VCroot_kmax.
- Modifying WaterStorage affects simultaneously Vleaf and Vsapwood from paramsWaterStorage.
- Modifying c from paramsTranspiration affects simultaneously VCleaf_c, VCstem_c and VCroot_c.
- Modifying d from paramsTranspiration affects simultaneously VCleaf_d, VCstem_d and VCroot_d.
- Modifying Plant_kmax from paramsTranspiration affects VCleaf_kmax, VCstem_kmax, VCroot_kmax and belowLayers$VCroot_kmax.
- Modifying Al2As from paramsAnatomy affects Vsapwood in paramsWaterStorage, VCstem_kmax and VCroot_kmax of paramsTranspiration and belowLayers$VCroot_kmax.
- Setting paramName = "Vmax298/Jmax298" affects both Vmax298 and Jmax298 from paramsTranspiration.

### Value

If `summary.fun = NULL` the function returns a list whose elements are the result of calling `spwb`. Otherwise, the function applies `summary.fun` to each simulation result and returns these summaries (actually, a call to `sapply` is done).

```

---

## `Stand values` *Stand values*

---

### Description

Functions to calculate stand attributes of a `forest` object.

### Usage

```
stand_basalArea(x, minDBH = 7.5)
stand_dominantTreeHeight(x, minDBH = 7.5)
stand_dominantTreeDiameter(x, minDBH = 7.5)
stand_quadraticMeanTreeDiameter(x, minDBH = 7.5)
stand_hartBeckingIndex(x, minDBH = 7.5)
stand_foliarBiomass(x, SpParams, gdd = NA, mode = "MED")
stand_fuel(x, SpParams, gdd = NA, includeDead = TRUE, mode = "MED")
stand_LAI(x, SpParams, gdd = NA, mode = "MED")
stand_phytovolume(x, SpParams)
```

## Arguments

| | |
|---|---|
| x | An object of class forest. |
| minDBH | Minimum diameter at breast height (in cm) to include in estimation. |
| SpParams | A data frame with species parameters (see SpParamsMED). |
| gdd | Growth degree days (to account for leaf phenology effects). |
| includeDead | A flag to indicate that standing dead fuels (dead branches) are included. |
| mode | Calculation mode, either "MED" or "US". |

## Value

- stand_basalArea: Stand basal area (m2/ha).
- stand_dominantTreeDiameter: Dominant tree diameter, i.e the average diameter of the 100 widest trees (in cm).
- stand_quadraticMeanTreeDiameter: Quadratic mean tree diameter, i.e. the diameter value corresponding to the current basal area and density.
- stand_dominantTreeHeight: Dominant tree height, i.e the average height of the 100 tallest trees (in cm).
- stand_hartBeckingIndex: Hart becking index.
- stand_foliarBiomass: Standing biomass of leaves (in kg/m2).
- stand_fuel: Stand fine fuel load (in kg/m2).
- stand_LAI: Stand leaf area index (m2/m2).
- stand_phytovolume: Stand shrub phytovolume (m3/m2).

```

summary.spwb *Summarises simulation results*

## Description

Function summary summarizes the model's output in different temporal steps (i.e. weekly, annual, ...).

## Usage

```
## S3 method for class 'pwb'
summary(object, freq="years", output="WaterBalance", FUN=sum, bySpecies = FALSE, ...)
## S3 method for class 'spwb'
summary(object, freq="years", output="WaterBalance", FUN=sum, bySpecies = FALSE, ...)
## S3 method for class 'growth'
summary(object, freq="years", output="WaterBalance", FUN=sum, bySpecies = FALSE, ...)
## S3 method for class 'fordyn'
summary(object, freq="years", output="WaterBalance", FUN=sum, bySpecies = FALSE, ...)
```

## Arguments

| | |
|---|---|
| object | An object of class spwb, pwb, growth or fordyn. |
| freq | Frequency of summary statistics (see cut.Date). |
| output | The data table to be summarized. Accepted values are the path to data tables in object, such as 'WaterBalance', 'Soil', 'Stand' or 'Plants$LAI'. It is also possible to use strings like 'Transpiration' and the function will interpret it as 'Plants$Transpiration'. |
| FUN | The function to summarize results (e.g., sum, mean, ...) |
| bySpecies | Allows aggregating output by species before calculating summaries (only has an effect with some values of output). Aggregation can involve a sum (as for plant lai or transpiration) or a LAI-weighted mean (as for plant stress or plant water potential). |
| ... | Additional parameters for function summary. |

## Note

When applied to fordyn objects, the summary function can be used to gather the results of different yearly steps into a single table while keeping a daily resolution (i.e. using freq = "days".

```

## Arguments

| | |
|---|---|
| v | Proportion of fine roots within each soil layer. |
| krhizomax | Maximum rhizosphere hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| kxylemmax | Maximum xylem hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| kleafmax | Maximum leaf hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| kstemmax | Maximum stem xylem hydraulic conductance (defined as flow per leaf surface unit and per pressure drop). |
| E | Flow per surface unit. |
| Emax | Maximum flow per surface unit. |
| Erootcrown | Flow per surface unit at the root crown. |
| psi | Water potential (in MPa). |
| psiPrev | Water potential (in MPa) in the previous time step. |
| psiDownstream | Water potential upstream (in MPa). |
| psiUpstream | Water potential upstream (in MPa). In a one-component model corresponds to soil potential. In a two-component model corresponds to the potential inside the roots. |
| psiCav | Minimum water potential (in MPa) experienced (for irreversible cavitation). |
| minFlow | Minimum flow in supply function. |
| psiPlant | Plant water potential (in MPa). |
| hydraulicNetwork | List with the hydraulic characteristics of nodes in the hydraulic network. |
| psiFineRoot | Water potential (in MPa) inside fine roots. |
| psiSoil | Soil water potential (in MPa). A scalar or a vector depending on the function. |
| psiRhizo | Soil water potential (in MPa) in the rhizosphere (root surface). |
| psiRootCrown | Soil water potential (in MPa) at the root crown. |

| | |
|---|---|
| psiStep | Water potential precision (in MPa). |
| psiTol | Precision for water potential estimates (in MPa). |
| psiIni | Vector of initial water potential values (in MPa). |
| psiMax | Minimum (maximum in absolute value) water potential to be considered (in MPa). |
| pCrit | Critical water potential (in MPa). |
| PLCprev | Previous proportion of loss conductance [0-1]. |
| V | Capacity of the compartment per leaf area (in L/m2). |
| fapo | Apoplastic fraction (proportion) in the segment. |
| pi0 | Full turgor osmotic potential (MPa). |
| eps | Bulk modulus of elasticity (MPa). |
| dE | Increment of flow per surface unit. |
| ETol | Precision for water flow per surface unit. |
| c, d | Parameters of the Weibull function (generic xylem vulnerability curve). |
| stemc, stemd | Parameters of the Weibull function for stems (stem xylem vulnerability curve). |
| leafc, leafd | Parameters of the Weibull function for leaves (leaf vulnerability curve). |
| n, alpha, l | Parameters of the Van Genuchten function (rhizosphere vulnerability curve). |
| allowNegativeFlux | A boolean to indicate wether negative flux (i.e. from plant to soil) is allowed. |
| maxNsteps | Maximum number of steps in the construction of supply functions. |
| ntrial | Maximum number of steps in Newton-Raphson optimization. |
| x | An object of class spwbInput. |
| type | Plot type for hydraulics_supplyFunctionPlot, either "E", "ERhizo", "psiStem", "psiRoot", "psiRhizo" or "dEdP"). |
| draw | A flag to indicate whether the supply function should be drawn or just returned. |
| speciesNames | A flag to indicate the use of species names instead of cohort names in plots. |
| ylim | Graphical parameter to override function defaults. |
| timestep | Time step in seconds. |

## Details

Function hydraulics_supplyFunctionPlot draws a plot of the supply function for the given soil object and network properties of each plant cohort in x. Function hydraulics_vulnerabilityCurvePlot draws a plot of the vulnerability curves for the given soil object and network properties of each plant cohort in x.

## Value

Values returned for each function are:

- `hydraulics_E2psiXylem`: The plant (leaf) water potential (in MPa) corresponding to the input flow, according to the xylem supply function and given an upstream (soil or root) water potential.
- `hydraulics_E2psiVanGenuchten`: The root water potential (in MPa) corresponding to the input flow, according to the rhizosphere supply function and given a soil water potential.
- `hydraulics_E2psiTwoElements`: The plant (leaf) water potential (in MPa) corresponding to the input flow, according to the rhizosphere and plant supply functions and given an input soil water potential.
- `hydraulics_E2psiNetwork`: The rhizosphere, root crown and plant (leaf water potential (in MPa) corresponding to the input flow, according to the vulnerability curves of rhizosphere, root and stem elements in a network.
- `hydraulics_Ecrit`: The critical flow according to the xylem supply function and given an input soil water potential.
- `hydraulics_EVanGenuchten`: The flow (integral of the vulnerability curve) according to the rhizosphere supply function and given an input drop in water potential (soil and rhizosphere).
- `hydraulics_EXylem`: The flow (integral of the vulnerability curve) according to the xylem supply function and given an input drop in water potential (rhizosphere and plant).
- `hydraulics_supplyFunctionOneXylem`, `hydraulics_supplyFunctionTwoElements` and `hydraulics_supplyFunc` A list with different numeric vectors with information of the two-element supply function:
  - `E`: Flow values (supply values).
  - `FittedE`: Fitted flow values (for `hydraulics_supplyFunctionTwoElements`).
  - `Elayers`: Flow values across the roots of each soil layer (only for `hydraulics_supplyFunctionNetwork`).
  - `PsiRhizo`: Water potential values at the root surface (only for `hydraulics_supplyFunctionNetwork`).
  - `PsiRoot`: Water potential values inside the root crown (not for `hydraulics_supplyFunctionOneXylem`).
  - `PsiPlant`: Water potential values at the canopy (leaf).
  - `dEdP`: Derivatives of the supply function.
- `hydraulics_supplyFunctionPlot`: If `draw = FALSE` a list with the result of calling `hydraulics_supplyFunctionNet` for each cohort.
- `hydraulics_regulatedPsiXylem`: Plant water potential after regulation (one-element loss function) given an input water potential.
- `hydraulics_regulatedPsiTwoElements`: Plant water potential after regulation (two-element loss function) given an input soil water potential.

psiVec = seq(-0.1, -7.0, by =-0.01)

#Vulnerability curve
kstem = unlist(lapply(psiVec, hydraulics_xylemConductance, kstemmax, stemc, stemd))
plot(-psiVec, kstem, type="l",ylab="Xylem conductance (mmol·m-2·s-1·MPa-1)",
xlab="Canopy pressure (-MPa)", lwd=1.5,ylim=c(0,kstemmax))
```

---

# tissuemoisture *Tissue moisture functions*

---

## Description

Set of functions used to calculate tissue moisture from water potential and viceversa.

## Usage

```
moisture_symplasticRWC(psiSym, pi0, epsilon)
moisture_symplasticPsi(RWC, pi0, epsilon)
moisture_apoplasticRWC(psiApo, c, d)
moisture_apoplasticPsi(RWC, c, d)
moisture_turgorLossPoint(pi0, epsilon)
moisture_tissueRWC(psiSym, pi0, epsilon,
                   psiApo, c, d,
                   af, femb = 0)
moisture_pressureVolumeCurvePlot(x, segment="leaf",
                    fraction = "all",
                    psiVec =  seq(-0.1, -8.0, by =-0.01),
                    speciesNames = FALSE)
moisture_sapwoodWaterCapacity(Al2As, height, V, L, wd)
moisture_leafWaterCapacity(SLA, ld)
```

## Arguments

| | |
|---|---|
| psiSym, psiApo | Symplastic or apoplastic water potential (MPa). |
| RWC | Relative water content [0-1]. |
| pi0 | Full turgor osmotic potential (MPa). |
| epsilon | Bulk modulus of elasticity (MPa). |
| c,d | Parameters of the xylem vulnerability curve. |
| af | Apoplastic fraction (proportion) in the segment (e.g. leaf or stem). |
| femb | Fraction of embolized conduits. |
| x | An object of class spwbInput. |
| segment | Segment whose relative water content curve to plot, either "stem" or "leaf". |
| fraction | Tissue fraction, either "symplastic", "apoplastic" or "all". |
| psiVec | Vector of water potential values to evaluate for the pressure-volume curve. |
| speciesNames | A flag to indicate the use of species names instead of cohort names in plots. |
| L | Vector with the length of coarse roots (mm) for each soil layer. |
| V | Vector with the proportion [0-1] of fine roots within each soil layer. |
| Al2As | Leaf area to sapwood area (in m2·m-2). |
| height | Plant height (in cm). |
| SLA | Specific leaf area (mm2·mg-1). |
| wd | Wood density (g·cm-3). |
| ld | Leaf tissue density (g·cm-3). |

## Value

Values returned for each function are:

- moisture_symplasticRWC: Relative water content [0-1] of the symplastic fraction.
- moisture_apoplasticRWC: Relative water content [0-1] of the apoplastic fraction.
- moisture_symplasticWaterPotential: Water potential (in MPa) of the symplastic fraction.
- moisture_apoplasticWaterPotential: Water potential (in MPa) of the apoplastic fraction.
- moisture_turgorLossPoint: Water potential (in MPa) corresponding to turgor loss point.
- moisture_segmentRWC: Segment relative water content [0-1].

# transp_maximumTranspirationModel

*Maximum transpiration vs. LAI*

---

## Description

Builds a model of maximum transpiration (Tmax) over potential evapotranspiration (PET) for increasing leaf area index (LAI) values for each plant cohort.

## Usage

```
transp_maximumTranspirationModel(x, meteo, latitude, elevation, slope, aspect,
                                 LAI_seq = c(0.1, 0.25, seq(0.5, 10, by = 0.5)),
                                 draw = TRUE)
```

## Arguments

| | |
|---|---|
| x | An object of class spwbInput, built using the 'Sperry' transpiration mode. |
| meteo | A data frame with daily meteorological data series. |
| latitude | Latitude (in degrees). |
| elevation, slope, aspect | Elevation above sea level (in m), slope (in degrees) and aspect (in degrees from North). |
| LAI_seq | Sequence of stand LAI values to be tested. |
| draw | Boolean flag to indicate plotting of results. |

## Details

This function performs a meta-modelling exercise using the Sperry transpiration model, with the aim to estimate coefficients for the equation used in the Granier transpiration model (Granier et al. 1999). The model to be fitted is: `y ~ a*LAI + b*LAI^2`, where `y` is the ratio between maximum transpiration (Tmax) and Penman's potential evapotranspiration (PET) and `LAI` is the stand LAI. Unlike the original equation of Granier et al. (1999), we fit a zero intercept model so that LAI = 0 translates into zero plant transpiration.

The function fits the model for each cohort separately, assuming it represents the whole stand. For each stand LAI value in the input sequence, the function uses simulations with Sperry transpiration

and the input weather to estimate y = Tmax/PET as a function of stand's LAI (deciduous stands include leaf phenology). Once simulations have been conducted for each stand LAI value, the function fits a Generalized Linear Model with the above equation, assuming a Gamma distribution of residuals and an identity link.

The coefficients of the model can be used to parametrize Granier's transpiration, since coefficients a and b in the equation above correspond to parameters Tmax_LAI and Tmax_LAIsq, respectively (see SpParamsMED).

## Value

Returns a list with as many elements as plant cohorts, each element being a glm model.

---

`transp_modes` *Transpiration modes*

---

## Description

High-level sub-models to represent transpiration, plant hydraulics and water relations within plants. The two submodels represent a very different degree of complexity, and correspond to Granier et al. (1999) or Sperry et al. (2017).

## Usage

```
transp_transpirationGranier(x, meteo, day,
                            latitude, elevation, slope, aspect,
                            modifyInput = TRUE)
transp_transpirationSperry(x, meteo, day,
                           latitude, elevation, slope, aspect,
                       canopyEvaporation = 0, snowMelt = 0, soilEvaporation = 0,
                           stepFunctions = NA,
                           modifyInput = TRUE)
```

## Arguments

| | |
|---|---|
| `x` | An object of class `spwbInput` or `growthInput`, built using the 'Granier' or 'Sperry' transpiration modes, depending on the function to be called. |
| `meteo` | A data frame with daily meteorological data series:<br>• `DOY`: Day of the year (Julian day).<br>• `Precipitation`: Precipitation (in mm).<br>• `MinTemperature`: Minimum temperature (in degrees Celsius).<br>• `MaxTemperature`: Maximum temperature (in degrees Celsius).<br>• `MinRelativeHumidity`: Minimum relative humidity (in percent).<br>• `MaxRelativeHumidity`: Maximum relative humidity (in percent).<br>• `Radiation`: Solar radiation (in MJ/m2/day).<br>• `WindSpeed`: Wind speed (in m/s). If not available, this column can be left with `NA` values. |
| `day` | An integer to identify a day within `meteo`. |
| `latitude` | Latitude (in degrees). |
| `elevation, slope, aspect` | Elevation above sea level (in m), slope (in degrees) and aspect (in degrees from North). |

`canopyEvaporation`
: Canopy evaporation (from interception) for `day` (mm).

`soilEvaporation`
: Bare soil evaporation for `day` (mm).

`snowMelt`
: Snow melt values for `day` (mm).

`stepFunctions`
: An integer to indicate a simulation step for which photosynthesis and profit maximization functions are desired.

`modifyInput`
: Boolean flag to indicate that the input `x` object is allowed to be modified during the simulation.

## Value

Function `transp_transpirationGranier` and `transp_transpirationSperry` return a list with the following elements:

- `"cohorts"`: A data frame with cohort information, copied from `spwbInput`.
- `"Stand"`: A vector of stand-level variables.
- `"Plants"`: A data frame of results for each plant cohort. When using `transp_transpirationGranier`, element `"Plants"` includes:
  - `"LAI"`: Leaf area index of the plant cohort.
  - `"LAIlive"`: Leaf area index of the plant cohort, assuming all leaves are unfolded.
  - `"AbsorbedSWRFraction"`: Fraction of SWR absorbed by each cohort.
  - `"Transpiration"`: Transpirated water (in mm) corresponding to each cohort.
  - `"GrossPhotosynthesis"`: Gross photosynthesis (in gC/m2) corresponding to each cohort.
  - `"psi"`: Water potential (in MPa) of the plant cohort (average over soil layers).
  - `"DDS"`: Daily drought stress [0-1] (relative whole-plant conductance).

  When using `transp_transpirationSperry`, element `"Plants"` includes:
  - `"LAI"`: Leaf area index of the plant cohort.
  - `"LAIlive"`: Leaf area index of the plant cohort, assuming all leaves are unfolded.
  - `"Extraction"`: Water extracted from the soil (in mm) for each cohort.
  - `"Transpiration"`: Transpirated water (in mm) corresponding to each cohort.
  - `"GrossPhotosynthesis"`: Gross photosynthesis (in gC/m2) corresponding to each cohort.
  - `"NetPhotosynthesis"`: Net photosynthesis (in gC/m2) corresponding to each cohort.
  - `"RootPsi"`: Minimum water potential (in MPa) at the root collar.
  - `"StemPsi"`: Minimum water potential (in MPa) at the stem.
  - `"StemPLC"`: Proportion of conductance loss in stem.
  - `"LeafPsiMin"`: Minimum (predawn) water potential (in MPa) at the leaf (representing an average leaf).
  - `"LeafPsiMax"`: Maximum (midday) water potential (in MPa) at the leaf (representing an average leaf).
  - `"LeafPsiMin_SL"`: Minimum (predawn) water potential (in MPa) at sunlit leaves.
  - `"LeafPsiMax_SL"`: Maximum (midday) water potential (in MPa) at sunlit leaves.

  - "LeafPsiMin_SH": Minimum (predawn) water potential (in MPa) at shade leaves.
  - "LeafPsiMax_SH": Maximum (midday) water potential (in MPa) at shade leaves.
  - "dEdP": Overall soil-plant conductance (derivative of the supply function).
  - "DDS": Daily drought stress [0-1] (relative whole-plant conductance).
  - "StemRWC": Relative water content of stem tissue (including symplasm and apoplasm).
  - "LeafRWC": Relative water content of leaf tissue (including symplasm and apoplasm).
  - "LFMC": Live fuel moisture content (in percent of dry weight).
  - "WaterBalance": Plant water balance (extraction - transpiration).
- "Extraction": A data frame with mm of water extracted from each soil layer (in columns) by each cohort (in rows).

  The remaining items are only given by transp_transpirationSperry:
- "EnergyBalance": When using the 'Sperry' transpiration mode, the model performs energy balance of the stand and 'EnergyBalance' is a list with the following:
  - "Temperature": A data frame with the temperature of the atmosphere ('Tatm'), canopy ('Tcan') and soil ('Tsoil.1', 'Tsoil.2', ...) for each time step.
  - "CanopyEnergyBalance": A data frame with the components of the canopy energy balance (in W/m2) for each time step.
  - "SoilEnergyBalance": A data frame with the components of the soil energy balance (in W/m2) for each time step.
- "RhizoPsi": Minimum water potential (in MPa) inside roots, after crossing rhizosphere, per cohort and soil layer.
- "Sunlitleaves" and "ShadeLeaves": Data frames for sunlit leaves and shade leaves and the following columns per cohort:
  - "LAI": Cumulative leaf area index of sunlit/shade leaves.
  - "Vmax298": Average maximum carboxilation rate for sunlit/shade leaves.
  - "Jmax298": Average maximum electron transport rate for sunlit/shade leaves.
- "ExtractionInst": Water extracted by each plant cohort during each time step.
- "PlantsInst": A list with instantaneous (per time step) results for each plant cohort:
  - "E": A data frame with the cumulative transpiration (mm) for each plant cohort during each time step.
  - "Ag": A data frame with the cumulative gross photosynthesis (gC/m2) for each plant cohort during each time step.
  - "An": A data frame with the cumulative net photosynthesis (gC/m2) for each plant cohort during each time step.
  - "Sunlitleaves" and "ShadeLeaves": Lists with instantaneous (for each time step) results for sunlit leaves and shade leaves and the following items:
    * "Abs_SWR": A data frame with instantaneous absorbed short-wave radiation (SWR).
    * "Net_LWR": A data frame with instantaneous net long-wave radiation (LWR).
    * "An": A data frame with instantaneous net photosynthesis (in micromol/m2/s).
    * "Ci": A data frame with instantaneous intercellular CO2 concentration (in ppm).
    * "GW": A data frame with instantaneous stomatal conductance (in mol/m2/s).
    * "VPD": A data frame with instantaneous vapour pressure deficit (in kPa).

    * "Temp": A data frame with leaf temperature (in degrees Celsius).
    * "Psi": A data frame with leaf water potential (in MPa).
  - "dEdP": A data frame with the slope of the plant supply function (an estimation of whole-plant conductance).
  - "RootPsi": A data frame with root crown water potential (in MPa) for each plant cohort during each time step.
  - "StemPsi": A data frame with stem water potential (in MPa) for each plant cohort during each time step.
  - "LeafPsi": A data frame with leaf (average) water potential (in MPa) for each plant cohort during each time step.
  - "StemPLC": A data frame with the proportion loss of conductance [0-1] for each plant cohort during each time step.
  - "StemRWC": A data frame with the (average) relative water content of stem tissue [0-1] for each plant cohort during each time step.
  - "LeafRWC": A data frame with the relative water content of leaf tissue [0-1] for each plant cohort during each time step.
  - "StemSympRWC": A data frame with the (average) relative water content of symplastic stem tissue [0-1] for each plant cohort during each time step.
  - "LeafSympRWC": A data frame with the relative water content of symplastic leaf tissue [0-1] for each plant cohort during each time step.
  - "PWB": A data frame with plant water balance (extraction - transpiration).
- "LightExtinction": A list of information regarding radiation balance through the canopy, as returned by function light_instantaneousLightExtinctionAbsortion.
- "CanopyTurbulence": Canopy turbulence (see wind_canopyTurbulence).
- "SupplyFunctions": If stepFunctions is not missing, a list of supply functions, photosynthesis functions and profit maximization functions.

```

---

# transp_stomatalregulation

*Stomatal regulation*

---

## Description

Set of high-level functions used in the calculation of stomatal conductance and transpiration. Function `transp_profitMaximization` calculates gain and cost functions, as well as profit maximization from supply and photosynthesis input functions. Function `transp_stomatalRegulationPlot` produces a plot with the cohort supply functions against water potential and a plot with the cohort photosynthesis functions against water potential, both with the maximum profit values indicated.

## Usage

```
transp_profitMaximization(supplyFunction, photosynthesisFunction, Gswmin, Gswmax)
transp_stomatalRegulationPlot(x, meteo, day, timestep,
                              latitude, elevation, slope = NA, aspect = NA,
                              type="E")
```

## Arguments

| | |
|---|---|
| `supplyFunction` | Water supply function (see `hydraulics_supplyFunctionNetwork`). |
| `photosynthesisFunction` | Function returned by `photo_photosynthesisFunction()`. |
| `Gswmin, Gswmax` | Minimum and maximum stomatal conductance to water vapour (mol·m-2·s-1). |
| `x` | An object of class `spwbInput` built using the 'Sperry' transpiration mode. |
| `meteo` | A data frame with daily meteorological data series. |
| `day` | An integer to identify a day within `meteo`. |
| `timestep` | An integer between 1 and `ndailysteps` specified in `x` (see `defaultControl`). |
| `latitude` | Latitude (in degrees). |
| `elevation, slope, aspect` | Elevation above sea level (in m), slope (in degrees) and aspect (in degrees from North). |
| `type` | A string with plot type, either `"E"` (transpiration flow), `"Ag"` (gross photosynthesis), `"An"` (net photosynthesis), `"Gsw"` (stomatal conductance to water vapour), `"T"` (temperature) or `"VPD"` (leaf vapour pressure deficit). |

## Value

Function `transp_profitMaximization` returns a list with the following elements:

- `Cost`: Cost function [0-1].
- `Gain`: Gain function [0-1].
- `Profit`: Profit function [0-1].
- `iMaxProfit`: Index corresponding to maximum profit (starting from 0).

`Vertical profiles` *Vertical profiles*

---

## Description

Functions to generate vertical profiles generated by an input `forest` object.

## Usage

```
vprofile_leafAreaDensity(x, SpParams = NULL, z = NULL, gdd = NA, mode = "MED",
                         byCohorts = FALSE, bySpecies = FALSE, draw = TRUE,
                         xlim = NULL)
vprofile_rootDistribution(x, SpParams, d = NULL,  bySpecies = FALSE, draw = TRUE,
                          xlim = NULL)
vprofile_fuelBulkDensity(x, SpParams, z = NULL, gdd = NA, mode = "MED",
                         draw = TRUE, xlim = NULL)
vprofile_PARExtinction(x, SpParams, z = NULL, gdd = NA, mode = "MED",
                       draw = TRUE, xlim = c(0,100))
vprofile_SWRExtinction(x, SpParams, z = NULL, gdd = NA, mode = "MED",
                       draw = TRUE, xlim = c(0,100))
vprofile_windExtinction(x, SpParams, u = 1, windMeasurementHeight = 200,
                        boundaryLayerSize = 2000, target = "windspeed",
                        z = NULL, gdd = NA, mode = "MED",
                        draw = TRUE, xlim = NULL)
```

## Arguments

| | |
|---|---|
| x | An object of class forest |
| SpParams | A data frame with species parameters (see SpParamsMED). |
| z | A numeric vector with height values. |
| d | A numeric vector with soil layer widths. |
| gdd | Growth degree days. |
| mode | Calculation mode, either "MED" or "US". |
| byCohorts | Separate profiles for each cohort. |
| bySpecies | Aggregate cohort profiles by species. |
| u | The value of measured wind speed (in m/s). |
| windMeasurementHeight | Height corresponding to wind measurement (in cm over the canopy). |
| boundaryLayerSize | Size of the boundary layer (in cm) over the canopy. |
| target | Wind property to draw, either "windspeed", "kineticenergy" (turbulent kinetic energy) or "stress" (Reynold's stress). |
| draw | Logical flag to indicate that a plot is desired. |
| xlim | Limits of the x-axis. |

## Value

A numeric vector with values measured at each height. Units depend on the profile function:

- vprofile_leafAreaDensity: Cumulative LAI (m2/m2) per height bin.
- vprofile_fuelBulkDensity: Fuel bulk density (kg/m3) per height bin.
- vprofile_PARExtinction: Percent of photosynthetically active radiation (%) corresponding to each height.
- vprofile_SWRExtinction: Percent of shortwave radiation (%) corresponding to each height.
- vprofile_windExtinction: Wind speed (m/s) corresponding to each height.

---

# waterUseEfficiency *Water use efficiency*

---

## Description

Calculates plant water use efficiency (WUE), at different temporal scales, from simulation results.

## Usage

```
waterUseEfficiency(x, type = "Plant Ag/E", leaves = "average", freq = "days",
                        draw = TRUE, ylim = NULL)
```

## Arguments

| | |
|---|---|
| x | An object of class spwb, pwb, growth or fordyn. |
| type | A string to indicate the scale of WUE calculation. Either:<br>• "Leaf iWUE": Leaf intrinsic WUE, i.e. instantaneous ratio between photosynthesis and stomatal conductance (only for simulations with transpirationMode = "Sperry" and subdailyResults = TRUE).<br>• "Leaf Ci": Leaf intercellular CO2 concentration (only for simulations with transpirationMode = "Sperry" and subdailyResults = TRUE).<br>• "Plant An/E": Plant (cohort) net photosynthesis over plant transpiration (only for simulations with transpirationMode = "Sperry")<br>• "Stand An/E": Stand net photosynthesis over stand transpiration (only for simulations with transpirationMode = "Sperry")<br>• "Plant Ag/E": Plant (cohort) gross photosynthesis over plant transpiration<br>• "Stand Ag/E": Stand gross photosynthesis over stand transpiration |
| leaves | Either "sunlit", "shade" or "average". Refers to the WUE of different leaf types or the average (with weights according to the LAI of sunlit and shade leaves). Only relevant for type = "iWUE". |

| | |
|---|---|
| freq | Frequency of summary statistics (see cut.Date). |
| draw | A boolean flag to indicate that a plot should be returned. |
| ylim | Range of values for y. |

## Details

Temporal aggregation of WUE values is done differently depending on the value of type. For type = "Plant Ag/E", type = "Stand Ag/E", type = "Plant An/E" and type = "Stand An/E" sums or daily photosynthesis and transpiration are first calculated at the desired temporal scale and the ratio is calculated afterwards. For type = "Leaf iWUE" intrinsic WUE values are first calculated at the daily scale (as averages of instantaneous An/gs ratios weighted by An) and then they are aggregated to the desired scale by calculating weighted averages, where weights are given by daily photosynthesis.

## Value

If draw=TRUE a plot is returned. Otherwise, the function returns a matrix with WUE values, where rows are dates (at the desired temporal scale), and columns are plant cohorts. In the case of type = "Plant Ag/E", type = "Stand Ag/E", type = "Plant An/E" and type = "Stand An/E" values are in gC/L. In the case of type = "Leaf iWUE" values are in micromol of carbon per mmol of water.

# Wind models *Models for canopy turbulence*

---

## Description

Models for canopy turbulence by Katul et al (2004).

## Usage

```
wind_canopyTurbulenceModel(zm, Cx, hm, d0, z0, model = "k-epsilon")
wind_canopyTurbulence(zmid, LAD, canopyHeight,
                      u, windMeasurementHeight = 200, model = "k-epsilon")
```

## Arguments

| | |
|---|---|
| zm | A numeric vector with height values (m). |
| Cx | Effective drag = Cd x leaf area density. |
| hm | Canopy height (m). |
| d0 | Zero displacement height (m). |
| z0 | Momentum roughness height (m). |
| zmid | A numeric vector of mid-point heights (in cm) for canopy layers. |
| LAD | A numeric vector of leaf area density values (m3/m2). |
| canopyHeight | Canopy height (in cm). |
| u | Measured wind speed (m/s). |
| windMeasurementHeight | Height of wind speed measurement with respect to canopy height (cm). |
| model | Closure model. |

## Details

Implementation in Rcpp of the K-epsilon canopy turbulence models by Katul et al (2004) originally in Matlab code (https://nicholas.duke.edu/people/faculty/katul/k_epsilon_model.htm).

## Value

Function `wind_canopyTurbulenceModel` returns a data frame of vertical profiles for variables:

- `z1`: Height values.
- `U1`: U/u*, where U is mean velocity and u* is friction velocity.
- `dU1`: dUdz/u*, where dUdz is mean velocity gradient and u* is friction velocity.
- `epsilon1`: epsilon/(u^3/h) where epsilon is the turbulent kinetic dissipation rate, u* is friction velocity and h is canopy height.
- `k1`: k/(u*^2), where k is the turbulent kinetic energy and u* is friction velocity.
- `uw1`: <uw>/(u*^2), where <uw> is the Reynolds stress and u* is friction velocity.
- `Lmix1`: Mixing length.

Function `wind_canopyTurbulence` returns a data frame of vertical profiles for transformed variables:

- `zmid`: Input mid-point heights (in cm) for canopy layers.
- `u`: Wind speed (m/s).
- `du`: Mean velocity gradient (1/s).
- `epsilon`: Turbulent kinetic dissipation rate.
- `k`: Turbulent kinetic energy.
- `uw`: Reynolds stress.

## Wood formation *Wood formation*

---

### Description

Functions to initialize and expand a ring of tracheids to simulate secondary growth.

## Usage

```
woodformation_initRing()
woodformation_growRing(ring, psi, Tc,
                       Nc=8.85, phi0=0.13, pi0=-0.8, CRD0=8.3,
                       Y_P=0.05, Y_T=5.0, h=0.043*1.8, s=1.8)
woodformation_relativeExpansionRate(psi, Tc, pi, phi, Y_P, Y_T)
woodformation_temperatureEffect(Tc, Y_T=5.0, DHa=87.5e3, DSd=1.09e3, DHd=333e3)
woodformation_relativeGrowthRate(dbh1, dbh2, yeardiff, lower = -2, upper = 8)
```

## Arguments

| | |
|---|---|
| `ring` | An object of class `ring` returned by function `woodformation_initRing`. |
| `psi` | Water potential (in MPa). |
| `Tc` | Temperature in Celsius. |
| `Nc` | Number of active cells in the cambium. |
| `phi0` | Initial value of cell extensibility (in MPa-1 day-1) |
| `pi0` | Initial value of cell osmotic potential (in MPa) |
| `CRD0` | Initial value of cell radial diameter |
| `Y_P` | Turgor pressure yield threshold (in MPa) |
| `Y_T` | Temperature yield threshold (in Celsius) |
| `h` | Cell wall hardening coefficient (in day-1) |
| `s` | Cell wall softening coefficient (unitless) |
| `pi` | Osmotic potential (in MPa) |
| `phi` | Cell extensibility (in MPa-1 day-1) |
| `DHa, DSd, DHd` | Enthalpy of activation, enthalpy difference and entropy difference between the catalytically active and inactive states of the enzymatic system (Parent et al. 2010). |
| `dbh1, dbh2` | Initial and final diameter at breast height. |
| `yeardiff` | Interval between dbh measurements, in years. |
| `lower, upper` | Lower and upper bounds for root finding. |

## Value

Function `woodformation_initRing()` returns a list of class 'ring', that is a list containing a data frame `cells` and two vectors: `P` and `SA`. Dataframe `cells` contains the columns "formation_date", "phi", "pi" and "CRD" and as many rows as dates processed. Vectors `P` and `SA` contain, respectively, the number of cells produced and the sapwood area corresponding to the ring of cells (assuming a tangencial radius of 20 micrometers). Function `woodformation_growRing()` modifies the input 'ring' object according to the environmental conditions given as input. Function `woodformation_relativeExpansionRate()` returns a numeric scalar with the relative expansion rate. Function `woodformation_temperatureEffect()` returns a scalar between 0 and 1 reflecting the temperature effect on tissue formation rate. Function `woodformation_relativeGrowthRate` returns the annual growth rate, relative to cambium perimeter, estimated from initial and final diameter values.
